Advances in Logistics, Operations, and Management Science (ALOMS) Book Series

John Wang
Montclair State University, USA

ISSN:2327-350X
EISSN:2327-3518

MISSION

Operations research and management science continue to influence business processes, administration, and management information systems, particularly in covering the application methods for decision-making processes. New case studies and applications on management science, operations management, social sciences, and other behavioral sciences have been incorporated into business and organizations real-world objectives.

The **Advances in Logistics, Operations, and Management Science (ALOMS)** Book Series provides a collection of reference publications on the current trends, applications, theories, and practices in the management science field. Providing relevant and current research, this series and its individual publications would be useful for academics, researchers, scholars, and practitioners interested in improving decision making models and business functions.

COVERAGE

- Finance
- Information Management
- Computing and information technologies
- Decision analysis and decision support
- Marketing engineering
- Operations Management
- Risk Management
- Political Science
- Organizational Behavior
- Networks

This book is dedicated to the memory of my late father for the love and care that he always displayed for his family, and for teaching me the importance of humanitarianism. Also, to my beautiful wife, Olga, and our handsome sons, Darius and Cyrus, for filling my life with so much love, joy, and happiness.

Volume I

Section 1: Accounting, Finance, and Economics

Managerial Accounting and Organizational Performance: Evidence From Romanian Healthcare Companies.....	1
<i>Ionica Holban, European Academy of the Regions, Belgium</i>	
<i>Sorinel Căpușneanu, Dimitrie Cantemir Christian University of Bucharest, Romania</i>	
<i>Dan Ioan Topor, 1 Decembrie 1918 University, Romania</i>	
<i>Vasile Burja, 1 Decembrie 1918 University, Romania</i>	
<i>Loredana Elena Comănescu, Valahia University, Romania</i>	
The Potential Role of Intellectual Capital in the Process of Accounting Convergence.....	12
<i>Ionica Oncioiu, Titu Maiorescu University, Romania</i>	
Manipulating Business Performances by Creative Accounting.....	24
<i>Ionica Oncioiu, Titu Maiorescu University, Romania</i>	
<i>Traian Ovidiu Calotă, Titu Maiorescu University, Romania</i>	
<i>Alin Eliodor Tănase, Titu Maiorescu University, Romania</i>	
A Survey on Forensic Accounting	35
<i>Roseline Oluwaseun Ogundokun, Landmark University, Omu Aran, Nigeria</i>	
<i>Opeyemi Eytayo Ogundokun, Agricultural and Rural Management Training Institute, Ilorin, Nigeria</i>	
The Necessity of Acting in the Public Interest: Corruption and Fraud in the Public Sector	45
<i>Tuğba Uçma Uysal, Muğla Sıtkı Koçman University, Turkey</i>	
<i>Ceray Aldemir, Mugla Sıtkı Kocman University, Turkey</i>	

Technical Efficiency Through Innovative Methods and Estimations in Financial Markets.....	55
<i>Aikaterini Kokkinou, Higher Military Academy, Greece</i>	
Financing Digital Innovation for Sustainable Development.....	71
<i>Danilo Piaggese, Knowledge for Development (K4D), USA</i>	
<i>Helena Landazuri, Knowledge for Development (K4D), USA</i>	
Auction-Based Pricing in Cloud Environment	86
<i>Branka Mikavica, Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia</i>	
<i>Aleksandra Kostic-Ljubisavljevic, Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia</i>	
Taking a Peek Behind the Corporate Finance in China.....	98
<i>Rodica Gherghina, The Bucharest University of Economic Studies, Romania</i>	
<i>Ioana Duca, Titu Maiorescu University, Romania</i>	
<i>Gabriela Claudia Oncioiu, Titu Maiorescu University, Romania</i>	
Financial Education	110
<i>Sergio Camisón-Haba, Universitat de València, Spain</i>	
An Overview of Diversities in the Use of the Profit and Loss Statement.....	124
<i>Ionica V. Oncioiu, The University of Bucharest, Romania</i>	
<i>Traian Ovidiu Calotă, Titu Maiorescu University, Romania</i>	
<i>Alin Eliodor Tănase, Titu Maiorescu University, Romania</i>	
Neuroeconomic Perspectives for Economics.....	135
<i>Torben Larsen, University of Southern Denmark, Denmark</i>	
The Dynamics of Demographic and Macroeconomic Variables in India.....	152
<i>Sovik Mukherjee, St. Xavier's University, India</i>	
The Economics of Unemployment	170
<i>Jennie Larry Johnson, University of North Texas, USA</i>	
<i>Adil A. Khan, University of North Texas, USA</i>	
The Role of Technology in Thana-Capitalism.....	181
<i>Maximiliano Emanuel Korstanje, University of Palermo, Buenos Aires, Argentina</i>	

Section 2: Business and Organizational Development and Research

Organizational Policy Learning and Evaluation Using Monte Carlo Methods	195
<i>Clement Leung, Chinese University of Hong Kong, China</i>	
<i>Nikki Lijing Kuang, University of California, San Diego, USA</i>	
<i>Vienne W. K. Sung, Hong Kong Baptist University, Hong Kong</i>	

Understanding Organizational Development With a Continuum of Care Model.....	209
<i>Jaimie Jo Wai Chan, Yee Hong Centre for Geriatric Care, Canada</i>	
<i>Maria Chu, Yee Hong Centre for Geriatric Care, Canada</i>	
<i>Kwong Yuen Liu, Yee Hong Centre for Geriatric Care, Canada</i>	
Does the Organizational Change Induced by the Pre-Implementation of an IS Proceed as a Planned Process?.....	219
<i>Amira Sghari, PRISME Laboratory (LR18ES24), Faculty of Economics and Management, University of Sfax, Tunisia</i>	
<i>Jamil Chaabouni, SESAME University, Tunis, Tunisia</i>	
<i>Serge Baile, Toulouse Business School, France</i>	
Automating the Generation of Test Items	233
<i>Hollis Lai, University of Alberta, Canada</i>	
<i>Mark Gierl, University of Alberta, Canada</i>	
Organizational Knowledge and Administration Lessons From an ICT4D MOOC	245
<i>Leila Goosen, University of South Africa, South Africa</i>	
Preferences, Utility, Value-Driven Modeling, and Decision Support.....	262
<i>Yuri P. Pavlov, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria</i>	
<i>Rumen D. Andreev, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria</i>	
<i>Valentina T. Terzieva, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria</i>	
<i>Katia A. Todorova, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria</i>	
<i>Petia I. Kademova-Katzarova, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria</i>	
A Nematic Model for Transmedia Organizational Literacy	279
<i>Ray Gallon, The Transformation Society, France</i>	
<i>Maria Nieves Lorenzo Galés, The Transformation Society, Spain</i>	
<i>Michael Josefowicz, Prinترنت, New York, USA</i>	
The Organizational Culture in the Days Post 9/11: A Critical Insight	294
<i>Maximiliano Emanuel Korstanje, University of Palermo, Buenos Aires, Argentina</i>	
The Diversity Paradox.....	305
<i>J. Jacob Jenkins, California State University, Channel Islands, USA</i>	
Fab Labs: A Place for Innovation, Collaboration, and Creation?	317
<i>Diane-Gabrielle Tremblay, University of Quebec, Canada</i>	
<i>Arnaud Scaillerez, University of Moncton, Canada</i>	

The Role of Networks in Local Governance.....	327
<i>Eugenio Salvati, University of Pavia, Italy</i>	
The Relationship Between Performance Measures and Overall Performance in the Manufacturing Environment.....	341
<i>Raman Kumar, Chandigarh University, India</i>	
<i>Harwinder Singh, Guru Nanak Dev Engineering College, India</i>	
A Model for Success in Agribusiness in the Portuguese Context.....	355
<i>Carla Sofia Vicente Negrão, University of Coimbra, Portugal</i>	

Section 3: Business Digital Economy and Knowledge

The Business Transformation Framework on Knowledge and Intelligence-Driven Development (KIDD).....	373
<i>Antoine Trad, IBISTM, France</i>	
<i>Damir Kalpic, Faculty of Electrical Engineering and Computing, University of Zagreb, Croatia</i>	
Continuous Assurance as Digital Transformation Enabler of Audit, Risk Management, and Business Compliance.....	392
<i>Rui Pedro Figueiredo Marques, ISCA, University of Aveiro, Portugal</i>	
The Risk Assessment Enhancement Process at the Federal Deposit Insurance Corporation.....	407
<i>Rania Mousa, University of Evansville, USA</i>	
Artificial Intelligence as an Enabler for Developing Business Systems	421
<i>N. Raghavendra Rao, FINAIT Consultancy Services, India</i>	
Exploring the Possibility of Managing Knowledge With Business Process Management Software (BPMS)	433
<i>Alicia Martin-Navarro, INDESS, University of Cádiz, Spain</i>	
<i>María Paula Lechuga Sancho, INDESS, University of Cádiz, Spain</i>	
<i>José Aurelio Medina-Garrido, INDESS, University of Cádiz, Spain</i>	
ICT Measurement From Information Society to Digital Economy	448
<i>Gulnara Abdrakhmanova, National Research University Higher School of Economics, Russia</i>	
<i>Leonid Gokhberg, National Research University Higher School of Economics, Russia</i>	
<i>Alexander Sokolov, National Research University Higher School of Economics, Russia</i>	
Organizational Knowledge of Digital Economy in Transformation, in Big Data, and in Internet of Things	463
<i>Vardan Mkrtchian, HHH University, Australia</i>	
<i>Serge Chernyshenko, Open University for the Humanities and Economics, Russia</i>	

Augmenting Organizational Knowledge Management Using Geographic Information Systems	477
<i>Colbert Mutiso Jackson, University of the Witwatersrand, South Africa</i>	
<i>Dickson Kinoti Kibetu, Chuka University, Kenya</i>	
Data Science for Business Analytics and Business Intelligence.....	495
<i>Matthias Lederer, International School of Management (ISM), Munich, Germany</i>	
<i>Patrick Schmid, International School of Management (ISM), Munich, Germany</i>	
Big Data, Data Management, and Business Intelligence.....	509
<i>Richard T. Herschel, Saint Joseph's University, USA</i>	
Human Face to Data as a Contemporary Approach to Decision Making in the Development Sector	520
<i>Ishret Binte Wahid, CARE, Bangladesh</i>	
<i>Mohammad Raquibul Hasan, CARE, Bangladesh</i>	
<i>Walter Mwasaa, CARE, Bangladesh</i>	

Volume II

Data Discovery Systems for Not-for-Profit Organizations.....	536
<i>Joanna Palonka, University of Economics in Katowice, Poland</i>	
Agile Stage-Gate Hybrid Framework for New Product Development.....	549
<i>Fotis C. Kitsios, University of Macedonia, Greece</i>	
<i>Maria Kamariotou, University of Macedonia, Greece</i>	

Section 4: Business Information Systems

Research Trends in Information Systems From the Management Discipline Based on Co-Occurrence Analysis	565
<i>Beatriz Forés, Universitat Jaume I, Spain</i>	
<i>Rafael Lapiedra, Universitat Jaume I, Spain</i>	
<i>José-María Fernández-Yáñez, Universitat Jaume I, Spain</i>	
Organizations Operating in Real Time (Real-Time Enterprise) and the Role of IT as a Tool Supporting Their Management Systems	582
<i>Jerzy Kisielnicki, Faculty of Management, University of Warsaw, Poland</i>	
<i>Marek Michal Markowski, Faculty of Management, University of Warsaw, Poland</i>	
Interfacing Communication and ICTs in a Divisionalised Structure: Effects on Good Governance..	597
<i>Toyosi Olugbenga Samson Owolabi, Lagos State University, Nigeria</i>	
<i>Godspower Godwin Itemeh, Ekiti State University, Nigeria</i>	
Information Technology in Mining Services Applications.....	615
<i>Pankaj Kumar Mishra, CSIR-Central Institute of Mining and Fuel Research, Dhanbad, India</i>	

An Approach for Estimating the Opportunity Cost Using Temporal Association Rule Mining and Clustering.....	631
<i>Reshu Agarwal, Department of Computer Science, G. L. Bajaj Institute of Technology and Management, Greater Noida, India</i>	
Systems, Services, Solutions of the Public Cloud	644
<i>Eduardo Correia, Ara Institute of Canterbury, New Zealand</i>	
Hatchery Unit and Six Sigma Methodology	653
<i>Asawaree Anand Hable, MAEER's Maharashtra Institute of Pharmacy, India</i>	
<i>Jaydip Rokade, Central Avian Research Institute, India</i>	
<i>Monika M., Central Avian Research Institute, India</i>	
<i>Gopi M., Central Avian Research Institute, India</i>	
Designing a Business Analytics Culture in Organizations in India	670
<i>Tanushri Banerjee, Pandit Deendayal Petroleum University, India</i>	
<i>Arindam Banerjee, Indian Institute of Management, Ahmedabad, India</i>	
Review and Evaluation of Systems Supporting Data Journalism.....	679
<i>Georgios Vassis, Hellenic Open University, Greece</i>	
<i>Dimitrios G. Margounakis, Hellenic Open University, Greece</i>	
<i>Efthimios Tambouris, University of Macedonia, Greece</i>	
From the Data to the Statistical Analysis of Football: The Case of the Italian Serie A League.....	695
<i>Alessio Drivet, Geogebra Institute of Turin, Italy</i>	
Automatic Detection of Semantic Clusters in Glossaries	711
<i>Marcela Ridao, Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina</i>	
<i>Jorge Horacio Doorn, Universidad Nacional del Oeste, Argentina & Universidad Nacional de Tres de Febrero, Argentina</i>	
An Improved Monkey Search Algorithm to Solve the Flexible Job Shop Scheduling Problems With Makespan Objective.....	728
<i>Mariappan Kadarkarainadar Marichelvam, Mepco Schlenk Engineering College, India</i>	
<i>Geetha M., Kamaraj College of Engineering and Technology, India</i>	
MDTF: A Most Dependent Transactions First Priority Assignment Heuristic	742
<i>Sarvesh Pandey, Madan Mohan Malaviya University of Technology, India</i>	
<i>Udai Shanker, Madan Mohan Malaviya University of Technology, India</i>	

Section 5: Business Policy, Ethics, and Law

What Is a P2P Business Model?	758
<i>Djamchid Assadi, Burgundy School of Business, France</i>	

Strategic Foresight Tools for Planning and Policy.....	775
<i>Barbara Jane Holland, Brooklyn Public Library, USA</i>	
The Influence of Technology on the Strategic Planning Process.....	798
<i>Martin K. Mayer, The University of North Carolina at Pembroke, USA</i>	
<i>Michael L. Martin, Town of Cary (NC) Fire Department, USA</i>	
Viability of the Sustainable Development Ecosystem	812
<i>Jay Hays, Independent Researcher, Brisbane, Australia</i>	
<i>Hayo Reinders, King Mongkut's University of Technology Thonburi, Thailand</i>	
Corporate Social Responsibility, Irresponsibility, and Citizenship	830
<i>Duane Windsor, Rice University, USA</i>	
Corporate Social Responsibility and Management in a Glocal Context.....	847
<i>Maria Luísa Silva, Universidade Aberta, Portugal</i>	
<i>Marc M. Jacquinet, Universidade Aberta, Portugal</i>	
<i>Ângela Lacerda Nobre, CICE, Instituto Politécnico de Setúbal, Portugal & CEFI, Universidade Católica Portuguesa, Portugal</i>	
Enriching Organisational Knowledge of Corporate Social Responsibility From the Traditional African-Nigerian and Islamic Religion Perspectives.....	860
<i>Lukman Raimi, American University of Nigeria, Nigeria</i>	
<i>Abdussalam Aljadani, Taibah University, Saudi Arabia</i>	
Understanding Corporate Social Responsibility of Commercial Banks in Nepal	874
<i>Raghu Bir Bir Bista, Tribhuvan University, Nepal</i>	
What Can Organizations Do to Combat Human Trafficking?	887
<i>Laura Dryjanska, Biola University, USA</i>	
A Guide to Cracking Down Cyber-Ethical Dilemmas.....	900
<i>Wanbil William Lee, The Computer Ethics Society, Hong Kong & Wanbil & Associates, Hong Kong</i>	
Algorithms and Bias	918
<i>Julie M. Smith, University of North Texas, USA</i>	
Gender and Urban Local Government in Bangladesh	933
<i>Fardaus Ara, Rajshahi University, Bangladesh</i>	

Section 6: Business Technological Innovations

ICT, Smart Systems, and Standardization	950
<i>Kai Jakobs, RWTH Aachen University, Germany</i>	

Digital Organizations Enhancement With Information and Operational Technologies Convergence.....	966
<i>Fjodor Ruzic, Institute for Informatics, Zagreb, Croatia</i>	
Network Organizations as a Catalyst for Innovation.....	982
<i>Olga I. Sobolewska, Warsaw University of Technique, Poland</i>	
<i>Jerzy A. Kisielnicki, Warsaw University, Poland</i>	
How IT-Enabled Dynamic Capabilities Add Value to the Development of Innovation Capabilities .	999
<i>Rogier van de Wetering, Open University, The Netherlands</i>	
<i>Maaïke Besuyen, Albert Heijn, The Netherlands & Open University, The Netherlands</i>	
Toward a Fitness Landscape Model of Firms' IT-Enabled Dynamic Capabilities	1017
<i>Rogier van de Wetering, Open University, The Netherlands</i>	
<i>Rik Bos, Open University, The Netherlands</i>	
Vertical Integration in Content Provisioning With Cloud Migration	1031
<i>Branka Mikavica, Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia</i>	
<i>Aleksandra Kostic-Ljubisavljevic, Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia</i>	
Impact of Management Automation on the Processing of Business Information	1045
<i>Alicia Martín-Navarro, INDESS, Spain & University of Cádiz, Spain</i>	
<i>María Paula Lechuga Sancho, INDESS, Spain & University of Cádiz, Spain</i>	
<i>Paula Algaba Berro, University of Cádiz, Spain</i>	
Management Support Systems Type Business Intelligence (BI) and Factors Determining Their Implementation	1059
<i>Jerzy Kisielnicki, Warsaw University, Poland</i>	
<i>Anna Maria Misiak, Warsaw University of Technology, Poland</i>	
REA-Semantic Teaching in the Accounting Information Systems (AIS) Courses.....	1075
<i>Husam A. Abu-Khadra, Roosevelt University, USA</i>	
<i>Shamsul I. Chowdhury, Roosevelt University, USA</i>	

Volume III

Embodied Conversation: A Personalized Conversational HCI Interface for Ambient Intelligence .	1091
<i>Andrej Zgank, University of Maribor, Slovenia</i>	
<i>Izidor Mlakar, University of Maribor, Slovenia</i>	
<i>Uros Berglez, University of Maribor, Slovenia</i>	
<i>Danilo Zimsek, University of Maribor, Slovenia</i>	
<i>Matej Borko, AI Slovenija, Slovenia</i>	
<i>Zdravko Kacic, University of Maribor, Slovenia</i>	
<i>Matej Rojc, University of Maribor, Slovenia</i>	

Integrated Electronic HEI Performance Management	1108
<i>Teay Shawyun, King Saud University, Saudi Arabia</i>	
Integrating Big Data Technology Into Organizational Decision Support Systems	1132
<i>Ahmad M. Kabil, University of Wisconsin-Whitewater, USA</i>	
Data Mining for Fraud Detection.....	1150
<i>Roberto Marmo, Universita' Pavia, Italy</i>	
Art Innovative Systems for Value Tagging	1163
<i>Laurel Powell, University of North Carolina at Charlotte, USA</i>	
<i>Anna Gelich, University of North Carolina at Charlotte, USA</i>	
<i>Zbigniew W. Ras, University of North Carolina at Charlotte, USA</i>	

Section 7: Cyber and Network Security

Designing an Effective Information Security Policy for Public Organizations: ISO 27001 as a Success Framework.....	1176
<i>Yassine Maleh, University Sultan Moulay Slimane, Morocco</i>	
<i>Mustapha Belaisaoui, Hassan 1st University, Morocco & National School of Business and Management in Settat (ENCG), Morocco</i>	
Auditor Evaluation and Reporting on Cybersecurity Risks.....	1194
<i>Jeffrey S. Zanzig, Jacksonville State University, USA</i>	
<i>Guillermo A. Francia III, University of West Florida, USA</i>	
Threat and Risk Assessment Using Continuous Logic.....	1212
<i>Aristides Dasso, Universidad Nacional de San Luis, Argentina</i>	
<i>Ana Funes, Universidad Nacional de San Luis, Argentina</i>	
Phishing Attacks in Mobile Platforms	1228
<i>Thangavel M., Thiagarajar College of Engineering, India</i>	
<i>Yaamine A. M., Thiagarajar College of Engineering, India</i>	
<i>Nandhini J. T., Thiagarajar College of Engineering, India</i>	
Blockchain Technology and Its Applications	1247
<i>Ting Wang, Indiana University South Bend, USA</i>	
<i>Liguo Yu, Indiana University South Bend, USA</i>	
<i>Yingmei Li, Harbin Normal University, China</i>	
Cyber Crime Threats, Strategies to Overcome, and Future Trends in the Banking Industry	1261
<i>Atul Bamrara, Department of School Education, Government of Uttarakhand, India</i>	

Cybersecurity Risks in Romanian Companies.....	1274
<i>Anca Gabriela Petrescu, Valahia University, Romania</i>	
<i>Marius Petrescu, Valahia University, Romania</i>	
<i>Ioana Panagore, Valahia University, Romania</i>	
<i>Florentina Raluca Bîlcan, Valahia University, Romania</i>	

Section 8: E-Business

Emerging E-Business Models and Their Impact	1286
<i>Liguo Yu, Indiana University South Bend, USA</i>	
<i>Ting Wang, Indiana University South Bend, USA</i>	
Digital Technologies in Wholesaling and Retailing	1297
<i>Felix Weber, University of Duisburg-Essen, Germany</i>	
eLancing the Future Work Model: Opportunities and Challenges	1313
<i>A. Mohammed Abubakar, Antalya Bilim University, Turkey</i>	
Value Network View on Digital Marketplace	1328
<i>Mohammad Nabil Almunawar, Universiti Brunei Darussalam, Brunei</i>	
<i>Muhammad Anshari, Universiti Brunei Darussalam, Brunei</i>	
<i>Syamimi Ariff Lim, Universiti Brunei Darussalam, Brunei</i>	
Crowdsourcing Maturity and Its Application in Public Organization Management	1340
<i>Regina Anna Lenart-Gansiniec, Jagiellonian University, Poland</i>	
Theory and Practice of Search Engine Optimization.....	1354
<i>Dimitrios Giomelakis, Aristotle University of Thessaloniki, Greece</i>	
<i>Andreas Veglis, Aristotle University of Thessaloniki, Greece</i>	
Techniques for Developing Mobile-Friendly Web Sites.....	1368
<i>J. Christopher Sandvig, Western Washington University, USA</i>	
Internet Banking Encounter Quality of Arab Middle East Banks: Organizational Determinants	1379
<i>Yazan Khalid Abed-Allah Migdadi, Qatar University, Qatar</i>	
<i>Ola Maher Al Omari, Yarmouk University, Jordan</i>	

Section 9: Entrepreneurship and SMEs

Entrepreneurship: Concept and Theoretical Framework	1394
<i>Jose Manuel Saiz-Alvarez, EGADE Business School, Tecnologico de Monterrey, Mexico, &</i>	
<i>Universidad Católica de Santiago de Guayaquil, Ecuador</i>	
Social Entrepreneurship.....	1413
<i>Soraya Husain-Talero, Corporacion Universitaria Minuto de Dios, Colombia</i>	
<i>Luz Dary González Cortés, Universidad de la Salle, Colombia</i>	

Entrepreneurial Personality: To Be or Not to Be an Entrepreneur	1427
<i>Brizeida R. Hernández-Sánchez, Department of Social Psychology, University of Salamanca, Spain</i>	
<i>Jose C. Sánchez-García, University of Salamanca, Spain</i>	
<i>Alexander Ward, University of Salamanca, Spain</i>	
Entrepreneurial Education	1443
<i>Sergio Camisón-Haba, Universitat de València, Spain</i>	
Designing the Future of Romanian Women Entrepreneurship: Fight and Flight	1457
<i>Delia Mioara Popescu, Valahia University, Romania</i>	
<i>Ionica Oncioiu, Titu Maiorescu University, Romania</i>	
<i>Anca Gabriela Petrescu, Valahia University, Romania</i>	
<i>Marius Petrescu, Valahia University, Romania</i>	
Avatar-Based Intellectual Managing for Innovation Technologies Transfer in Nationals Entrepreneurships of Armenia	1468
<i>Vardan Mkrttchian, HHH University, Australia</i>	
<i>Serge Chernyshenko, Open University for the Humanities and Economics, Russia</i>	
<i>Mikhail Ivanov, Financial University Under the Government of the Russian Federation, Russia</i>	
Understanding SME Techno-Entrepreneurship in Nigeria's IT Clusters.....	1480
<i>Immanuel Ovemeso Umukoro, Lagos Business School, Pan-Atlantic University, Nigeria</i>	
The ISO/IEC 29110 Software Lifecycle Standard for Very Small Companies	1498
<i>Rory V. O'Connor, Dublin City University, Ireland</i>	
Design of a Strategic Knowledge Management Model to Evaluate Sales Growth in SMEs	1516
<i>Leonardo Bermon-Angarita, National University of Colombia, Colombia</i>	
<i>Lyda Jovanna Rueda-Caicedo, National University of Colombia, Colombia</i>	
A Theoretical Approach Exploring Knowledge Transmission Across Generations in Family SMEs.....	1531
<i>Filippo Ferrari, University of Bologna, Italy</i>	
Industry 4.0: A Strategy of the European Union and Germany to Promote the Manufacturing Industries – Opportunities and Challenges of Digitization.....	1551
<i>Immo H. Wernicke, German Government (Retired), Germany</i>	
IT Resources as Risk Mitigators: The Case of Spanish Bankrupt SMEs	1565
<i>Carlos Pineiro-Sanchez, Universidade da Coruña, Spain</i>	
<i>Pablo de Llano-Monelos, Universidade da Coruña, Spain</i>	
Role of Technology Startups in Africa's Digital Ecosystem	1580
<i>Benjamin Enahoro Assay, Delta State Polytechnic, Ogwashi-Uku, Nigeria</i>	

Knowledge in Science and Technology Parks	1598
<i>Ricardo Martínez-Canas, University of Castilla-La Mancha, Spain</i>	
<i>Pablo Ruiz-Palomino, University of Castilla-La Mancha, Spain</i>	
<i>Maria Angeles Garcia-Haro, Open University of Cataluña, Spain</i>	

Section 10: Hospitality, Travel, and Tourism Management

Internationalization in the Hotel Industry and Modes of Entry	1610
<i>Anna Sergiyvna Moskalenko, DEGEIT, University of Aveiro, Portugal</i>	
<i>Inês Cruz Reis da Silva, DEGEIT, University of Aveiro, Portugal</i>	
<i>Juliana Gonçalves, DEGEIT, University of Aveiro, Portugal</i>	
<i>Mafalda Brito, DEGEIT, University of Aveiro, Portugal</i>	
<i>António Carrizo Moreira, University of Aveiro, Portugal</i>	
Similarities and Differences Between Word-of-Mouth and Electronic Word-of-Mouth.....	1625
<i>María Dolores Sánchez-Fernández, Universidade da Coruña, Spain</i>	
<i>Daniel Álvarez-Bassi, Catholic University of Uruguay, Uruguay</i>	
<i>José Ramón Cardona, University of the Balearic Islands, Spain</i>	

Volume IV

Mobile Culture for Tourism Communication	1638
<i>Pedro Andrade, Institute of Social Sciences, Communication, and Society Research Centre, University of Minho, Portugal</i>	
The Integrated Tourism Analysis Platform (ITAP) for Tourism Destination Management	1651
<i>Francisco Sacramento Gutierrez, Centre Tecnologic de Catalunya, Big Data, and Data Science Unit, Eurecat, Spain</i>	
<i>Pedro Miguel Gomes, EEA Grants Unit, Secretary General for Environment and Energy Transition, Portugal</i>	
Exploring Terroir Zone and Tourism Cluster Based on GIS Mapping.....	1661
<i>Ya-Hui Hsueh, National Taichung University of Education, Taiwan</i>	
Marketing 4.0 and Internet Technologies in the Tourism Industry Context.....	1679
<i>María Ángeles García-Haro, Open University of Cataluña, Spain</i>	
<i>María Pilar Martínez-Ruiz, University of Castilla-La Mancha, Spain</i>	
<i>Ricardo Martínez-Cañas, University of Castilla-La Mancha, Spain</i>	
<i>Pablo Ruiz-Palomino, University of Castilla-La Mancha, Spain</i>	
Destination@-Branding and Re-Branding of Ten European Capitals.....	1690
<i>Elena Bocci, Sapienza University of Rome, Italy</i>	
<i>Annamaria Silvana de Rosa, Sapienza University of Rome, Italy</i>	
<i>Laura Dryjanska, Rosemead School of Psychology, Biola University, USA</i>	

Rapid Changes in Approaching First-Time Destination Historical Cities	1709
<i>Annamaria Silvana de Rosa, Sapienza University of Rome, Italy</i>	
<i>Elena Bocci, Sapienza University of Rome, Italy</i>	
<i>Laura Dryjanska, Biola University, USA</i>	
An Exploratory Study of In-Flight Safety Videos and Airline Marketing Strategy	1723
<i>Norita Ahmad, American University of Sharjah, UAE</i>	
<i>Nawal Al Ansaari, American University of Sharjah, UAE</i>	
Model/Anti-Model Advocacy Responses to Hospitality Industry Sexual Harassment	1736
<i>Jeffrey D. Brand, University of Northern Iowa, USA</i>	
<i>Gayle M. Pohl, University of Northern Iowa, USA</i>	

Section 11: Knowledge Management

Useful Organizational Knowledge via Knowledge Elicitation and Management.....	1750
<i>Ronald John Lofaro, Embry-Riddle Aeronautical University, USA</i>	
State of the Art in Semantic Organizational Knowledge	1762
<i>Mamadou Tadiou Kone, International University of Grand-Bassam, Côte d'Ivoire</i>	
Influential Factors on Reverse Knowledge Transfers in Multinational Organizations	1774
<i>Rita Marques Castro, University of Aveiro, Portugal</i>	
<i>Sara Pandeirada Neves, University of Aveiro, Portugal</i>	
<i>António Carrizo Moreira, University of Aveiro, Portugal</i>	
Knowledge Harvesting Concept Paves Way for Open Innovation Initiatives	1790
<i>N. Raghavendra Rao, FINAIT Consultancy Services, India</i>	
Information Overload.....	1805
<i>Tibor Koltay, Eszterhazy Karoly University, Hungary</i>	
Big Data Analytics and Mining for Knowledge Discovery	1817
<i>Carson K. Leung, University of Manitoba, Canada</i>	
Strategies for Increasing Knowledge Translation of Evidence-Based Practice in Athletic Training.....	1831
<i>Brittany V. Allard, Seton Hall University, USA</i>	
<i>Michelle D'Abundo, Seton Hall University, USA</i>	

Section 12: Management Science

Management Tools: From Complexity Reduction to Complexity Creation	1842
<i>Mazri Chabane, INERIS, France</i>	
Strategic Thinking.....	1857
<i>César Camisón, University of Valencia, Spain</i>	

Neurostrategy	1876
<i>César Camisón, University of Valencia, Spain</i>	
The Use of Design Thinking to Develop Corporate Skills and Competencies.....	1894
<i>Lucia Maria Cuque, Pontificia Universidade Católica de São Paulo, Brazil</i>	
<i>Joao Mattar, Pontificia Universidade Católica de São Paulo, Brazil</i>	
Managerial Challenges of Corporate Social Responsibility in Developing Countries.....	1907
<i>Ebrahim Soltani, Hamdan Bin Mohammed Smart University, UAE</i>	
<i>Ying Ying Liao, Hamdan Bin Mohammed Smart University, UAE</i>	
<i>Abdullah Iqbal, University of Kent, UK</i>

Chief Digital Officers and Their Roles, Agendas, and Competencies	1929
<i>Vladimir Korovkin, Moscow School of Management SKOLKOVO, Russia</i>	
Global Project Management: Achieving Sustainability in Diverse Multinational Organizational Development Initiatives	1941
<i>Emad Rahim, Bellevue University, USA</i>	
<i>Terrence Duncan, Bellevue University, USA</i>	
Managing Workplace Conflicts Through Self-Mediation.....	1953
<i>Ndifon Neji Obi, University of Calabar, Nigeria</i>	
Modern Downsizing.....	1970
<i>Grzegorz Wojtkowiak, The Poznan University of Economics and Business, Poland</i>	
Challenges of the Repatriation Process.....	1984
<i>Andreia Almeida Rodrigues, University of Aveiro, Portugal</i>	
<i>Rúben Daniel Coelho Lopes, University of Aveiro, Portugal</i>	
<i>Rúben Dinis Almeida, University of Aveiro, Portugal</i>	
<i>Adriana Coutinho Gradim, University of Aveiro, Portugal</i>	
<i>António Carrizo Moreira, University of Aveiro, Portugal</i>	
Maturity Models in Healthcare IS/IT Investments: Challenges and Trends.....	1997
<i>Jorge Gomes, ADVANCE, ISEG, Universidade de Lisboa, Portugal</i>	
<i>Mário Romão, ADVANCE, ISEG, Universidade de Lisboa, Portugal</i>	
Impact of Employees' Empowerment on Perceived Quality of Service Delivery in the Tertiary Health Institutions.....	2014
<i>Michael Abayomi Fowowe, Ekiti State University, Ado-Ekiti, Nigeria</i>	
<i>Kayode K. Arogundade, Ekiti State University, Ado-Ekiti, Nigeria</i>	
Women at Leadership Positions in Bangladesh Civil Service	2031
<i>Fardaus Ara, Rajshahi University, Bangladesh</i>	

Section 13: Marketing and Customer Relationship Management

Green Marketing	2043
<i>Teresa Paiva, NECE, CI&DEI, Guarda Polytechnic Institute, Portugal</i>	
Internet of Packaging and the Bridge Between Digital Marketing and Physical Retailing	2057
<i>Justina Lydekaityte, Aarhus University, Denmark</i>	
<i>Torben Tambo, Aarhus University, Denmark</i>	
Intelligent Assistants and the Internet of Things as the Next Marketing Landscape.....	2071
<i>Edward Forrest, University of Alaska, Anchorage, USA</i>	
<i>Christina McDowell Marinchak, University of Alaska, Anchorage, USA</i>	
<i>Bogdan Hoanca, University of Alaska, Anchorage, USA</i>	
Automation of Marketing Processes and the Discovery of Knowledge for CRM	2086
<i>Milena Janakova, Silesian University in Opava, Czech Republic</i>	
Developed E-CRM Intelligence in Technological Trends	2095
<i>Bashar Shahir Ahmed, Computer Science and Systems Engineering Laboratory, University</i>	
<i>Abdelmalek Essaadi, Morocco</i>	
<i>Mohammed Al-Sarem, Information System Department, Taibah University, Saudi Arabia</i>	
<i>Mohamed Larbi Ben Maati, Computer Science and Systems Engineering Laboratory,</i>	
<i>University Abdelmalek Essaadi, Morocco</i>	
Critical Success Factors in a Six Dimensional Model CRM Strategy	2105
<i>José Duarte Santos, CEOS.PP, Polytechnic of Porto, Portugal</i>	
<i>José Pita Castelo, Universidade de Vigo, Spain</i>	
<i>Fernando Almeida, INESC TEC, University of Porto, Portugal & Polytechnic Higher</i>	
<i>Institute of Gaya, Portugal</i>	
The New Technological Trends in Customer Relationship Management (CRM) to Unveil Opportunities for Developing Countries.....	2119
<i>Cagla Seneler, Yeditepe University, Turkey</i>	
<i>Rana Kadioglu, Yeditepe University, Turkey</i>	
A Comparison Between Inbound and Outbound Marketing	2129
<i>Mohammad Izzuddin Mohammed Jamil, Universiti Brunei Darussalam, Brunei</i>	
<i>Mohammad Nabil Almunawar, Universiti Brunei Darussalam, Brunei</i>	
Micro Organization Use of Social Media for Business-to-Business Customers	2140
<i>Lisa S. Rufer, Rider University, USA</i>	
<i>Rosalyn J. Rufer, Empire State College (SUNY), USA</i>	
<i>Savita Hanspal, State University of New York at Potsdam, USA</i>	
Social Media Mining.....	2153
<i>Roberto Marmo, Universita' Pavia, Italy</i>	

The Ubiquitous Role of Mobile Phones in Value Co-Creation Through Social Media Marketing ..	2166
<i>Syed Far Abid Hossain, College of Business Administration, International University of Business Agriculture and Technology, Bangladesh</i>	
<i>Xu Shan, Xi'an Jiaotong University, China</i>	
<i>Abdul Qadeer, Xi'an Jiaotong University, China</i>	

Volume V

Crisis Communication in the Age of Social Media and the Case of Dairy Khoury	2181
<i>Nisrine Zammar, Faculty of Information, Lebanese University, Lebanon</i>	
Social Advertisements and Recall.....	2197

Examining the Value, Satisfaction, and Loyalty Relationship Under Online Framework Using PLS-ANN.....	2224
<i>Himanshu Sharma, University of Delhi, India</i>	
<i>Anu G. Aggarwal, University of Delhi, India</i>	
<i>Abhishek Tandon, University of Delhi, India</i>	
Emotional Intelligence and Customer Satisfaction of Online Health Information	2251
<i>Ionica Holban, European Academy of the Regions, Belgium</i>	
<i>Ioana Duca, Titu Maiorescu University, Romania</i>	
<i>Rodica Gherghina, The Bucharest University of Economic Studies, Romania</i>	
<i>Diana Andreea Mândricel, Titu Maiorescu University, Romania</i>	
<i>Elena Denisa Nicolescu, Valahia University, Romania</i>	
When Do Working Consumers Become Prosumers? Exploring Prosumer Characteristics for Organizational Value Creation Strategies	2261
<i>Sabina Alina Potra, Politehnica University Timisoara, Romania</i>	
<i>Adrian Pugna, Politehnica University Timisoara, Romania</i>	
Eye Tracker Technology in Sports Sponsorship Research.....	2278
<i>Ho Keat Leng, Nanyang Technological University, Singapore</i>	
<i>Philip Phua, Nanyang Technological University, Singapore</i>	

Section 14: Operations and Service Management

Business Process Management	2287
<i>Matthias Lederer, International School of Management (ISM), Munich, Germany</i>	
<i>Peter Schott, REHAU AG+Co, Germany</i>	
Artificial Neural Network in Operation Management Regarding Communication Issue	2303
<i>Ayan Chatterjee, S. P. Jain Institute of Management and Research (SPJIMR), India</i>	
<i>Susmita Sarkar, Bangabasi Evening College, India</i>	
<i>Mahendra Rong, Bangabasi Evening College, India</i>	
<i>Debmallya Chatterjee, S. P. Jain Institute of Management and Research (SPJIMR), India</i>	
Enablers of Servitization Roles and Action Mechanism	2321
<i>Flair Karaki, Al Quds Open University, Palestine</i>	
Ambient-Intelligent Decision Support System (Am-IDSS) for Smart Manufacturing.....	2338
<i>Marzieh Khakifirooz, Tecnológico de Monterrey, Mexico</i>	
<i>Mahdi Fathi, University of North Texas, USA</i>	
<i>Yiannis Ampatzidis, University of Florida, USA</i>	
<i>Panos M. Pardalos, University of Florida, USA</i>	
Decision Support for Smart Manufacturing.....	2352
<i>Marzieh Khakifirooz, Tecnológico de Monterrey, Mexico</i>	
<i>Mahdi Fathi, University of North Texas, USA</i>	
<i>Panos M. Pardalos, University of Florida, USA</i>	
<i>Daniel J. Power, University of Northern Iowa, USA</i>	
Modelling Quality and Pricing in Next Generation Telecom Networks.....	2365
<i>Vesna Radonjic Djogatovic, Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia</i>	
<i>Marko Djogatovic, Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia</i>	
Resources, Recycling, Regulations, and Reputation in the Comparison of Operations Sustainability Techniques	2378
<i>Alan D. Smith, Robert Morris University, USA</i>	
RFID Technologies and Warehouse Applications: Case Studies.....	2393
<i>Alan D. Smith, Robert Morris University, USA</i>	
Green Supply Chains and Enabling RFID Technology	2403
<i>Alan D. Smith, Robert Morris University, USA</i>	
Environmental Friendliness in Low Carbon Supply Chain and Operations	2421
<i>Muhammad Shabir Shaharudin, Universiti Malaysia Pahang, Malaysia</i>	
<i>Yudi Fernando, Universiti Malaysia Pahang, Malaysia</i>	

A Review of Future Energy Efficiency Measures and CO2 Emission Reduction in Maritime Supply Chain.....	2431
<i>Muhamad Fairuz Ahmad Jasmi, Faculty of Business and Management, Universiti Teknologi MARA (UiTM), Puncak Alam, Malaysia</i>	
<i>Yudi Fernando, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
Big Data Analytics in Supply Chain Management	2443
<i>Nenad Stefanovic, Faculty of Science, University of Kragujevac, Serbia</i>	
Critical Success Factors of Analytics and Digital Technologies Adoption in Supply Chain	2458
<i>Debashish Roy, AIMA AMU, India</i>	
Blockchain for Supply Chain Management: Opportunities, Technologies, and Applications.....	2472
<i>Nenad Stefanovic, Faculty of Technical Sciences Cacak, University of Kragujevac, Serbia</i>	
Adoption of Blockchain Technology to Improve Integrity of Halal Supply Chain Management	2488
<i>Yudi Fernando, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Mohd Ridzuan Darun, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Ahmed Zainul Abideen, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Daing Nasir Ibrahim, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Marco Tieman, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Fazeeda Mohamad, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
Role of Smart Contracts in Halal Supply Chain Management	2497
<i>Yudi Fernando, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Mohd Ridzuan Darun, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Basheer Al-haimi, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Daing Nasir Ibrahim, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Marco Tieman, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
<i>Fazeeda Mohamad, Faculty of Industrial Management, Universiti Malaysia Pahang, Malaysia</i>	
Wasta Effects on Supply Chain Relationships in the Middle East Region	2505
<i>Noor Al-Ma'aitah, Mutah University, Jordan</i>	
<i>Ebrahim Soltani, Hamdan Bin Mohammed Smart University, UAE</i>	
<i>Ying-Ying Liao, Hamdan Bin Mohammed Smart University, UAE</i>	

Section 15: Organizational Management and Communications

Types and Challenges of Expatriation	2522
<i>Carla Freitas Morence, University of Aveiro, Portugal</i>	
<i>Marta Ferreira Esteves, University of Aveiro, Portugal</i>	
<i>Núria Rodrigues Silva, University of Aveiro, Portugal</i>	
<i>António Carrizo Moreira, University of Aveiro, Portugal</i>	
Digital Transformation Journeys: The Future Is Now	2533
<i>Jurgen Janssens, asUgo Consulting, Belgium</i>	
Strategic HRM and Organizational Agility Enable Firms to Respond Rapidly and Flexibly to the Changing Environment	2551
<i>Nibedita Saha, University Institute, Tomas Bata University in Zlin, Czech Republic</i>	
Learning Organisation: An Effect on Organisational Performance	2570
<i>Chandra Sekhar Patro, Gayatri Vidya Parishad College of Engineering (Autonomous), India</i>	
Unified Communication Technologies at a Global Automotive Organization	2592
<i>Anthony D. Bolton, University of South Africa, South Africa</i>	
<i>Leila Goosen, University of South Africa, South Africa</i>	
<i>Elmarie Kritzinger, University of South Africa, South Africa</i>	
Social Media and Organizational Communication	2609

Preface

Technological innovations of the past few decades have had significant impacts on modern organizations worldwide forcing many of them to reevaluate their current infrastructures in terms of both efficiency and effectiveness. As the opportunity for further innovation progresses the goal of any organization is to identify more advanced and streamlined methods for managing organizational resources, human resources, as well as structural aspects. Successful organizations have been able to design and implement technology-driven infrastructures allowing them to use the most updated information in managing their resources to the level of accuracy and efficiency that until a few years ago was not imaginable!

The ushering in of the Fourth Industrial Revolution has been a catalyst to those companies that have not been able to reap the benefits of integrating modern technological innovation in support of managing their organizations more effectively. In modern times, many firms have begun looking into Artificial Intelligence (AI) in managing vast organizational knowledge to identify the most effective solutions, techniques, and management practices. The application and utilization of AI can now be found in most industries such as healthcare, education, engineering, tourism, government, transportation, retail, finance, etc. and offers many innovative and cost-effective solutions which are ultimately making organizations in these industries much more efficient and competitive.

Becoming a technology-driven organization does not just happen simply by acquiring technology resources and equipment, but rather begins through visionary leadership. Specifically, leadership that provides clear direction for the creation of a very innovative technology-centered infrastructure where technological evolution can be turned into a driving force in managing the organization. To ensure that an organization stays technology-driven, all administrative and management practices within the organization need to be continually assessed and redesigned in support of ongoing progress and sustainability of the organization. Regrettably, many organizations fail to understand that to properly utilize and benefit from technological innovations, they must have a modern administrative and management infrastructure in place, otherwise a lack thereof is a recipe for disaster.

Over the years, there have been many failures of technology experts – including a failure to understand that technological resources are not just hardware and software, but also humanware which includes all human elements from those in management to the end users who plan, implement, and manage technology applications and utilization. Also, a failure to understand how important it is to organizational leadership to develop state-of-the-art management practices where all human needs for utilizing the technology are carefully planned and managed. Technology-driven organizations cannot become successful unless there are strong modern management practices in place to support technological deployments. Therefore, modern successful organizations need to revolutionize their administrative and management practices first to pave the way for technology to become the driving force within their organization.

During the past few decades, there has been much research conducted by experts all over the world in determining what the critical factors are for developing successful technology-driven organizations. Much of the research has been centered around the human elements, organizational structures, management leadership and vision, as well as the impacts of external forces such as the economy and government policies, continuously expanding the body of literature in their important research areas. To provide access to some of the most valuable research findings relevant to organizational knowledge, administration, and technologies, the need to create a single publication where all this research can be found is of paramount importance. As such, this comprehensive five-volume *Encyclopedia of Organizational Knowledge, Administration, and Technology (First Edition)*, was created and is designed to act as a single all-encompassing reference source on conceptual, methodological, and technical aspects of organizational knowledge and management and will provide insight into emerging topics including, but not limited to: organizational structure, strategic leadership, information technology management, business analytics, corporate social responsibility, supply chain management, and social networking. The chapters within this publication are aimed to provide researchers with contemporary research findings and results that are sure to pave the way for future research and discoveries pertaining to the creation of technology-driven organizations all over the globe.

The five-volume *Encyclopedia of Organizational Knowledge, Administration, and Technology (First Edition)* is organized into fifteen sections that provide comprehensive coverage of important topics. These sections are: 1) **Accounting, Finance, and Economics**, 2) **Business and Organizational Development and Research**, 3) **Business Digital Economy and Knowledge**, 4) **Business Information Systems**, 5) **Business Policy, Ethics, and Law**, 6) **Business Technological Innovations**, 7) **Cyber and Network Security**, 8) **E-Business**, 9) **Entrepreneurship and SMEs**, 10) **Hospitality, Travel, and Tourism Management**, 11) **Knowledge Management**, 12) **Management Science**, 13) **Marketing and Custom Relationship Management**, 14) **Operations and Service Management**, 15) **Organizational Management and Communications**.

Each of the focused sections include diverse chapters centered around a common theme, with each of the chapters then arranged by relevance to the theme and to each other. Two different tables of contents support the reader with navigating the contents by volume and alphabetically. Also, technical and managerial terms and their definitions are offered in addition to thorough reference sections.

SECTION 1: ACCOUNTING, FINANCE, AND ECONOMICS

This section opens this extensive reference source by highlighting the latest trends in the financial sector, from accounting practices to corporate finance and neuroeconomics. One of the initial chapters in the section, “**The Potential Role of Intellectual Capital in the Process of Accounting Convergence**,” authored by Prof. Ionica Oncioiu from Titu Maiorescu University, Romania, explores the importance of reviewing the fiscal policy of intangible assets in order to reestablish profit growth and promote business development. A following chapter, “**Technical Efficiency Through Innovative Methods and Estimations in Financial Markets**,” authored by Dr. Aikaterini Kokkinou from the Higher Military Academy, Greece, investigates technical efficiency estimation in financial markets, using both parametric and non-parametric techniques: parametric Stochastic Frontier Analysis (SFA) approach or non-parametric Data Envelopment Analysis (DEA). It focuses on reviewing the stochastic frontier analysis literature regarding estimating inefficiency in financial markets level, as well as explaining producer heterogeneity

along with the relationships with productive efficiency level. Another chapter featured in this section, **“Financing Digital Innovation for Sustainable Development,”** authored by Dr. Danilo Piaggese and Mrs. Helena Landazuri from K4D (Evidence and Knowledge for Development), United States, discusses establishing technical and financial support for the promotion of digital innovation and economic sustainability through the use of market development and efficient business models. The chapter that follows this, **“Auction-Based Pricing in Cloud Environment,”** authored by Ms. Branka Mikavica and Prof. Aleksandra Kostic-Ljubisavljevic from the University of Belgrade, Serbia, analyzes the benefits of allocation mechanisms using cloud resources, as well as the effects of improved bidding strategies within auction-based pricing methods. One of the closing chapters in this section, **“Neuroeconomic Perspectives for Economics,”** authored by Prof. Torben Larsen from the University of Southern Denmark, Denmark, outlines three macroeconomic focus points: 1) Equality by Universal Basic Income, 2) Environmental Protection by Carbon Emission Tax, and 3) Individualized Stress-Management.

SECTION 2: BUSINESS AND ORGANIZATIONAL DEVELOPMENT AND RESEARCH

This section includes chapters that investigate various business models and strategies that promote business development and a positive organizational culture. The first chapter in the section, **“Organizational Policy Learning and Evaluation using Monte Carlo Methods,”** authored by Prof. Clement Leung from the Chinese University of Hong Kong, China, Ms. Nikki Lijing Kuang of the University of California, San Diego, United States, and Prof. Vienne Sung from Hong Kong Baptist University, Hong Kong, explains the deployment of learning strategies in given organizational environments for reinforcing policy evaluation and review and promoting effective operation. Another noteworthy chapter found in this section, **“The Diversity Paradox,”** authored by Prof. J. Jacob Jenkins from California State University Channel Islands, United States, studies the false attainment of organizational diversity by emphasizing a singular form of individualism while neglecting alternative expressions. The chapter that follows this, **“Fab Labs, A Place for Innovation, Collaboration and Creation?”** authored by Prof. Diane-Gabrielle Tremblay from the University of Quebec, Canada and Prof. Arnaud Scaillerez from the University of Moncton, Canada, evaluates the implementation of digital workshops for developing organizational innovation and improving creativity among employees. The subsequent chapter, **“The Role of Networks in Local Governance,”** authored by Prof. Eugenio Salvati from the University of Pavia, Italy, identifies the characteristics of governmental networks in local communities and their connection to innovation in public administration. The final chapter in this section, **“A Model for Success in Agribusiness in the Portuguese Context,”** authored by Prof. Carla Negrão from the University of Coimbra, Portugal, supports developing a theoretical framework of achievement for agribusiness in today’s digital economy through the application of novel factors including e-commerce, internationalization, and strategic alignment.

SECTION 3: BUSINESS DIGITAL ECONOMY AND KNOWLEDGE

This section presents coverage on the novel transformation of business practices with the implementation of digital systems. One of the opening chapters, **“Continuous Assurance as Digital Transformation Enabler of Audit, Risk Management, and Business Compliance,”** authored by Prof. Rui Pedro

Marques from the University of Aveiro, Portugal, provides an overview of continuous assurance services and its role in the evaluation and design of information systems, as well as the overall effectiveness of organizations. Another noteworthy chapter found in this section, **“Artificial Intelligence as an Enabler for Developing Business Systems,”** authored by Dr. N. Raghavendra Rao from FINAIT Consultancy Services, India, reviews the creation and improvement of modern business models using artificial intelligence. One of the chapters that succeeds this, **“Augmenting Organizational Knowledge Management Using Geographic Information Systems,”** authored by Prof. Colbert Jackson from the University of the Witwatersrand, South Africa and Prof. Dickson Kibetu from Chuka University, Kenya, examines the role of GIS technology in developing effective and efficient knowledge management systems within an organization. Another chapter featured within this section, **“Big Data, Data Management, and Business Intelligence,”** authored by Prof. Richard Herschel from Saint Joseph’s University, United States, studies the application of big data in facilitating sound business intelligence, as well as key issues and effectiveness of data management in organizations. One of the last chapters presented, **“Data Discovery Systems for Not-for-Profit Organizations,”** authored by Prof. Joanna Palonka from the University of Economics in Katowice, Poland, discusses the integration of information and communication technologies, specifically data discovery systems, in nonprofit organizations to promote effective resource management methods and enhanced quality of services.

SECTION 4: BUSINESS INFORMATION SYSTEMS

This section discusses coverage and research perspectives on analytical approaches for integrating computing tools into corporate operations. The earliest chapter featured in this section, **“Research Trends in Information Systems from the Management Discipline Based on Co-Occurrence Analysis,”** authored by Prof. Beatriz Forés, Prof. Rafael Lapiedra, and Mr. José-María Fernández-Yáñez from Jaume I University, Spain, studies the impact of information systems in business practices and organizational performance based on the analysis of concurrences of key words used in publications of the specific topic. The next chapter, **“Organizations Operating in Real Time (Real-Time Enterprise) and the Role of IT as a Tool Supporting their Management Systems,”** authored by Prof. Jerzy Kisielnicki and Mr. Marek Markowski from the University of Warsaw, Poland, examines the benefits of implementing real-time information processing into an organization and its impact on the production of IT systems. Also included within this section is the chapter, **“An Approach for Estimating the Opportunity Cost Using Temporal Association Rule Mining and Clustering,”** authored by Prof. Reshu Agarwal from the G.L. Bajaj Institute of Technology and Management, India, which breaks down the application of data mining on evaluating penalty cost and determining opportunity cost for ensuring optimal inventory management and control. Following this chapter is, **“Systems, Services, Solutions of the Public Cloud,”** authored by Prof. Eduardo Correia from the Ara Institute of Canterbury, New Zealand. This chapter dissects the various models and platforms of the public cloud that are available for organizations, as well as highlights security risks and challenges that might arise. One of the final chapters found in this section, **“Automatic Detection of Semantic Clusters in Glossaries,”** authored by Ms. Marcela Ridao from the Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina and Prof. Jorge Doorn of Universidad Nacional del Oeste, Argentina, improves upon traditional visualization techniques in natural language models by applying a cluster detection method.

SECTION 5: BUSINESS POLICY, ETHICS, AND LAW

This section provides trending research on the latest best practices involving strategic planning and policy and examines corporate social responsibility initiatives. One of the opening chapters presented in this section, **“The Influence of Technology on the Strategic Planning Process,”** authored by Prof. Martin Mayer from the University of North Carolina at Pembroke, United States and Deputy Fire Chief Michael Martin of the Town of Cary (NC) Fire Department, United States, deliberates the transformation of public-sector strategic planning and organizational dynamics with the application of digital technology, as well as future opportunities and challenges. A proceeding chapter, **“Corporate Social Responsibility, Irresponsibility, and Citizenship,”** authored by Prof. Duane Windsor from Rice University, United States, addresses key issues in the field of corporate social responsibility, as well as analyzes its economic, ethical, and strategic influences. One of the concluding chapters presented in this section, **“What Can Organizations Do to Combat Human Trafficking?”** authored by Prof. Laura Dryjanska from Biola University, United States, converses effective organizational management techniques for fighting forms of modern slavery, including supply chain management and corporate social responsibility. Another closing chapter, **“A Guide to Cracking Down Cyber-Ethical Dilemmas,”** authored by Dr. Wanbil Lee from The Computer Ethics Society and Wanbil & Associates, Hong Kong, provides extensive research on cyber ethics and how to solve related issues using modern theories and technologies. A finishing chapter that follows this, **“Algorithms and Bias,”** authored by Ms. Julie Smith from the University of North Texas, United States, investigates the issue of discriminatory bias in algorithms as well as optimal solutions in the minimization of this problem.

SECTION 6: BUSINESS TECHNOLOGICAL INNOVATIONS

This section features the latest technological innovations including business intelligence, data mining, and decision support system applications that are being implemented in organizational practices. The first chapter featured in this section, **“ICT, Smart Systems, and Standardization,”** authored by Prof. Kai Jakobs from RWTH Aachen University, Germany, provides trending research on the relationship between standardization management strategies and the innovative sectors of smart systems and information and communication technologies. Another chapter that can be found within this section, **“Impact of Management Automation on the Processing of Business Information,”** authored by Prof. Alicia Martín-Navarro, Prof. María Paula Lechuga Sancho, and Mrs. Paula Algaba Berro from the University of Cádiz, Spain, analyzes the application of information systems into business management and its correlation to organizational development. Another noteworthy chapter, **“Quantification of Semantic Intelligence,”** authored by Prof. Maria Koleva from the Bulgarian Academy of Sciences, Bulgaria, discusses the various characteristics of semantic intelligence and speculates if there is a universal method for accurately measuring it. A closing chapter in this section, **“Data Mining for Fraud Detection,”** authored by Prof. Roberto Marmo from the University of Pavia, Italy, reviews the rising concerns of fraud as well as methods within data mining that provide viable solutions. The concluding chapter, **“Art Innovative Systems for Value Tagging,”** authored by Ms. Laurel Powell, Prof. Anna Gelich, and Prof. Zbigniew Ras from the University of North Carolina at Charlotte, United States, examines the use of big data analytics and recommender systems for accurately appraising specific artworks.

SECTION 7: CYBER AND NETWORK SECURITY

This section features in-depth analyses on contemporary findings in digital security methods. One of the initial chapters featured, **“Auditor Evaluation and Reporting on Cybersecurity Risks,”** authored by Prof. Jeffrey Zanzig from Jacksonville State University, United States and Prof. Guillermo Francia, III from the University of West Florida, United States, explores the implementation of guidance programs within audit agencies in order to understand modern cybersecurity risks and develop capable identification and defense techniques. The ensuing chapter, **“Threat and Risk Assessment Using Continuous Logic,”** authored by Profs. Aristides Dasso and Ana Funes from the National University of San Luis, Argentina, researches the use of logistical methods for assessing the threats and risks associated with computer systems in an organization. Another chapter included within this section, **“Phishing Attacks in Mobile Platforms,”** authored by Prof. Thangavel M., Miss Yaamine A.M., and Miss Nandhini J.T. from the Thiagarajar College of Engineering, India, studies the prominent hacking method of phishing and its modern assault on mobile operating systems. One of the concluding chapters, **“Blockchain Technology and Its Applications,”** authored by Mr. Ting Wang and Prof. Liguu Yu from Indiana University South Bend, United States and Prof. Yingmei Li from Harbin Normal University, China, dissects the fundamentals of blockchain technology as well as analyzes its impact on various industrial fields. Another closing chapter, **“Cyber Crime Threats, Strategies to Overcome, and Future Trends in the Banking Industry,”** authored by Prof. Atul Bamrara from the Indira Gandhi National Open University, India, examines the countless security risks that accompany electronic banking and enhanced protection and defense methods the financial industry can use against white collar crime.

SECTION 8: E-BUSINESS

This section presents informative chapters on electronic business models and the management of company websites. One of the opening chapters in this section, **“Digital Technologies in Wholesaling and Retailing,”** authored by Mr. Felix Weber from the University of Duisburg-Essen, Germany, investigates the effect of technological trends and their underlying elements in empowering the transformation of wholesaling and the retail industry. The following chapter, **“eLancing the Future Work Model: Opportunities and Challenges,”** authored by Prof. A. Mohammed Abubakar from Antalya Bilim University, Turkey, contemplates the idea of altering traditional work perceptions and regulations through the implementation of online freelance labor, or “eLancing”. Another chapter that can be found within this section, **“Crowdsourcing Maturity and Its Application in Public Organization Management,”** authored by Prof. Regina Lenart-Gansinieć from Jagiellonian University, Poland, proposes an original and modern method for measuring crowdsourcing maturity within public administration bodies. The chapter that succeeds this, **“Theory and Practice of Search Engine Optimization,”** authored by Mr. Dimitrios Giomelakis and Prof. Andreas Veglis from the Aristotle University of Thessaloniki, Greece, provides an overview of the evolution of search engines, as well as trending practices and techniques in optimizing Internet search programs. One of the last chapters, **“Techniques for Developing Mobile-Friendly Web Sites,”** authored by Prof. J. Sandvig from Western Washington University, United States, discusses the current state of accessing webpages via mobile devices, as well as current attributes, popular design methods, and remaining limitations of mobile-friendly web sites.

SECTION 9: ENTREPRENEURSHIP AND SMEs

This section includes trending material and real-world studies on strategic approaches in the development of entrepreneurship, start-ups, and small and medium enterprises. An initial chapter identified in this section, **“Avatar-Based Intellectual Managing for Innovation Technologies Transfer in Nationals Entrepreneurships of Armenia,”** authored by Prof. Vardan Mkrttchian from HHH University, Australia, Prof. Serge Chernyshenko from Open University for the Humanities and Economics, Russian Federation, Prof. Mikhail Ivanov, Financial University under the Government of the Russian Federation, Russian Federation, and Prof. Leyla Gamidullaeva, Penza State University, Russian Federation, explains the promotion of sustainable economic growth, industrial competitiveness, and business attractiveness by facilitating the transfer of intellectual and innovative Internet technologies in the Republic of Armenia. Another recognized chapter, **“The ISO/IEC 29110 Software Lifecycle Standard for Very Small Companies,”** authored by Prof. Rory O’Connor from Dublin City University, Ireland, offers viable software development and improvement strategies for small organizations and start-up companies. The subsequent chapter, **“Design of a Strategic Knowledge Management Model to Evaluate Sales Growth in SMEs,”** authored by Prof. Leonardo Bermon-Angarita and Mrs. Lyda Rueda-Caicedo from the National University of Colombia, Colombia, proposes a knowledge management model for small and medium enterprises that analyzes marketing trends, promotes organizational learning in competitiveness, and evaluates the potential growth in sales. A chapter that follows this, **“A Theoretical Approach to Exploring Knowledge Transmission Across Generations in Family SMEs,”** authored by Prof. Filippo Ferrari from the University of Bologna, Italy, explores how knowledge is shared between the generations involved in business succession, along with cognitive and cultural insights on how this process can be improved. One of the final chapters presented, **“Role of Technology Startups in Africa’s Digital Ecosystem,”** authored by Mr. Benjamin Assay from Delta State Polytechnic Ogwashi-Uku, Nigeria, examines the overarching role that technology startup companies have in the progression and growth of digital systems and mobile Internet adoption in Africa.

SECTION 10: HOSPITALITY, TRAVEL, AND TOURISM MANAGEMENT

This section highlights the latest findings on marketing and branding strategies, as well as technological applications within the travel and tourism sector. The first chapter of this section, **“Internationalization in the Hotel Industry and Modes of Entry,”** authored by Profs. Anna Moskalenko, Inês Silva, Juliana Gonçalves, Mafalda Brito, and Antonio Carrizo Moreira from the University of Aveiro, Portugal, analyzes globalization methods of hotel chains in relation to principal theories of international business. Another featured chapter, **“The Integrated Tourism Analysis Platform (ITAP) for Tourism Destination Management,”** authored by Dr. Francisco Gutierrez from the Eurecat, Centre Tecnologic de Catalunya, Big Data & Data Science Unit, Spain and Mr. Pedro Gomes, Secretary General for Environment and Energy Transition, EEA Grants Unit, Portugal, demonstrates specific aspects of integrated geographical data within tourism planning for the promotion of interactive and innovative visitation experiences for travelers. Another chapter found within this section, **“Rapid Changes in Approaching First-Time Destination Historical Cities,”** authored by Profs. Annamaria de Rosa and Elena Bocci from Sapienza University of Rome, Italy and Prof. Laura Dryjanska from Biola University, United States, measures the social prominence of European cities by comparatively looking at a compilation of web-based media

information about these targeted areas from first-time visitors. The following chapter, **“An Exploratory Study of In-Flight Safety Videos and Airline Marketing Strategy,”** authored by Prof. Norita Ahmad and Mrs. Nawal AlAnsaari from the American University of Sharjah, United Arab Emirates, investigates the effectiveness of in-flight safety videos and analyzes them through a marketing approach in order to gauge passenger attentiveness. The concluding chapter presented in this section, **“Model/Anti-Model Advocacy Responses to Hospitality Industry Sexual Harassment,”** authored by Profs. Jeffrey Brand and Gayle Pohl from the University of Northern Iowa, United States, studies how organizations and industries can address accusations against members (anti-model) and also propose and advocate for changes (model) to improve symbolic and material conditions for their industry, their employees, and their stakeholder communities.

SECTION 11: KNOWLEDGE MANAGEMENT

This section provides extensive chapters on knowledge harvesting, sharing and transfer. A preliminary chapter in this section, **“State of the Art in Semantic Organizational Knowledge,”** authored by Prof. Mamadou Kone from the International University of Grand-Bassam, Ivory Coast, studies the use of semantic web and linked data technologies in supporting the creation and distribution of knowledge within organizations. The subsequent chapter, **“Influential Factors on Reverse Knowledge Transfers in Multinational Organizations,”** authored by Ms. Rita Castro, Miss Sara Neves, and Prof. António Moreira from the University of Aveiro, Portugal, provides extensive research on the transfer of knowledge within multinational organizations from subsidiary companies to the headquarters which can lead to the promotion of productivity, performance, and global strategy formulation. Another prominent chapter found in this section, **“Knowledge Harvesting Concept Paves Way for Open Innovation Initiatives,”** authored by Dr. N. Raghavendra Rao from FINAIT Consultancy Services, India, investigates the relationship between collaborative knowledge sharing within organizational networks and the development of open innovation initiatives. Following this chapter is **“Information Overload”** authored by Prof. Tibor Koltay from Eszterhazy Karoly University, Hungary, which reviews the nature and types of information overload, as well as provides measures for prevention and mitigating symptoms using information management and literacy capabilities. A closing chapter, **“Big Data Analytics and Mining for Knowledge Discovery,”** authored by Prof. Carson Leung from the University of Manitoba, Canada, focuses on the discovery of organizational knowledge by mining through large collections of data, as well as discussing various methods that would assist in achieving this task.

SECTION 12: MANAGEMENT SCIENCE

This section provides global perspectives on current advancements within managerial methods in enterprises. One of the first chapters in this section, **“The Use of Design Thinking to Develop Corporate Skills and Competencies,”** authored by Miss Lucia Cuque from Pontifícia Universidade Católica de São Paulo, Brazil and Prof. Joao Mattar from Pontifícia Universidade Católica de São Paulo (PUC-SP) and Centro Universitário Internacional Uninter, Brazil, discusses the promotion and development of 21st century skills for in the corporate environment using design thinking methodologies along with information and communication technologies. One of the ensuing chapters, **“Global Project Manage-**

ment: Achieving Sustainability in Diverse Multinational Organizational Development Initiatives,” authored by Profs. Emad Rahim and Terrence Duncan from Bellevue University, United States, examines the benefits of project management initiatives within an international context in order to improve organizational development. Following this chapter is **“Managing Workplace Conflicts Through Self-Mediation”** authored by Prof. Ndifon Obi from the University of Calabar, Nigeria, which researches how to effectively control conflict within the workplace by implementing self-mediation principles. Another highlighted chapter, **“Modern Downsizing,”** authored by Prof. Grzegorz Wojtkowiak from the Poznan University of Economics and Business, Poland, provides an in-depth review on the concept of downsizing which includes the evolution of the term, various directions of development, and future research trends of its use within the management field. The finishing chapter of this section, **“Women at Leadership Positions in Bangladesh Civil Service,”** authored by Prof. Fardaus Ara from Rajshahi University, Bangladesh, investigates the consistent lack of power and influence women have within the government of Bangladesh, despite their increasing presence in leadership roles.

SECTION 13: MARKETING AND CUSTOMER RELATIONSHIP MANAGEMENT

This section discusses explorative approaches and research perspectives on current innovations in promotional strategies and advertising. The opening chapter of this section, **“Green Marketing,”** authored by Prof. Teresa Paiva from Guarda Polytechnic Institute, Portugal, explores the evolution of marketing practices in order to achieve environmental sustainability while maintaining organizational success and customer satisfaction. A proceeding chapter that is featured, **“Intelligent Assistants and the Internet of Things as the Next Marketing Landscape,”** authored by Profs. Edward Forrest, Christina McDowell-Marinchak, and Bogdan Hoanca from the University of Alaska Anchorage, United States, examines the current adoption of smart technologies and the Internet of things within the business and marketing industry through the analysis of prominent applications of digital assistants in the field. Also found in this section is the chapter, **“The New Technological Trends in Customer Relationship Management (CRM) to Unveil Opportunities for Developing Countries,”** authored by Prof. Cagla Seneler and Miss Rana Kadioglu from Yeditepe University, Turkey, which discusses how the use of technological concepts including artificial intelligence, cloud computing, and the Internet of things are transforming the way organizations manage their relationship with customers, specifically in developing regions of the world. Following this, is the chapter, **“The Ubiquitous Role of Mobile Phones in Value Co-Creation Through Social Media Marketing,”** authored by Mr. Syed Hossain, Ms. Xu Shan, and Mr. Abdul Qadeer from Xi’an Jiaotong University, China. This chapter evaluates the contemporary function of mobile phones and social media in developing value co-creation and customer engagement strategies by surveying various universities in China and compiling primary data. A concluding chapter, **“Emotional Intelligence and Customers Satisfaction of Online Health Information,”** authored by Dr. Ionica Holban from the European Academy of the Regions, Belgium, Profs. Ioana Duca and Diana Andreea Mândricel from Titu Maiorescu University, Romania, Prof. Rodica Gherghina of The Bucharest University of Economic Studies, Romania, and Prof. Elena Nicolescu from Valahia University, Romania, researches online health service qualities that influence consumers’ behavioral intentions toward using health information systems in Romania and analyzes the congruence of digitalization in healthcare and the improvement of customer satisfaction.

SECTION 14: OPERATIONS AND SERVICE MANAGEMENT

This section presents extensive research and reportage on systematic advancements in operational tasks, supply chain management, and the service industry, as well as initiatives to reduce a company's carbon footprint. A primary chapter found in this section, **“Artificial Neural Network in Operation Management Regarding Communication Issue,”** authored by Mr. Ayan Chatterjee from S.P. Jain Institute of Management and Research, India, Miss Susmita Sarkar and Prof. Mahendra Rong from Bangabasi Evening College, India, and Prof. Debmallya Chatterjee of S P Jain Institute of Management & Research (SPJIMR), India, explores the different models of artificial neural networks and their ability to solve key communication issues in the operation management area. Another featured chapter, **“Decision Support for Smart Manufacturing,”** authored by Prof. Marzieh Khakifirooz from Tecnológico de Monterrey, Mexico, Prof. Mahdi Fathi from the University of North Texas, United States, Prof. Panos M. Pardalos from the University of Florida, United States, and Prof. Daniel J. Power from the University of Northern Iowa, United States, reviews the implementation of decision-making templates based on operations research modeling and optimization techniques in smart manufacturing environments. It aims to provide insights into the system engineering design, emphasizing system requirements analysis and specification, the use of alternative analytical methods and how systems can be evaluated. The next chapter, **“Green Supply Chains and Enabling RFID Technology,”** authored by Prof. Alan Smith from Robert Morris University, United States, studies the promotion of environmentally conscious business practices by incorporating radio-frequency identification tactics. Another chapter contained within this section, **“A Review of Future Energy Efficiency Measures and CO2 Emission Reduction in Maritime Supply Chain,”** authored by Profs. Muhamad Fairuz Ahmad Jasmi and Yudi Fernando from Universiti Malaysia Pahang, Malaysia, evaluates the adoption of low carbon technologies and other energy efficient practices within the shipping industry in order to reduce harmful emissions and preserve marine ecosystems. One of the concluding chapters, **“Big Data Analytics in Supply Chain Management,”** authored by Prof. Nenad Stefanovic from the University of Kragujevac, Serbia, discusses applications, challenges and new trends in supply chain big data analytics and background research of big data initiatives related to supply chain management is provided.

SECTION 15: ORGANIZATIONAL MANAGEMENT AND COMMUNICATIONS

This section contains integral research on novel communicative practices within professional firms and trending management perspectives. This section starts with the chapter, **“Types and Challenges of Expatriation,”** authored by Miss Carla Morence, Miss Marta Esteves, Miss Núria Silva, and Prof. António Moreira from the University of Aveiro, Portugal, which covers research on the contemporary perspectives of corporate migration and relocation within multinational enterprises. Another chapter found within this section, **“Strategic HRM and Organizational Agility Enable Firms to Respond Rapidly and Flexibly to the Changing Environment,”** authored by Prof. Nibedita Saha from Tomas Bata University in Zlín, Czech Republic, demonstrates how companies use agile capabilities including knowledge development and strategic human resource management to react and adapt to modern challenges within the business industry. Following this chapter is **“Social Media and Organizational Communication”** authored by Profs. Victor Briciu and Arabela Briciu from Transilvania University of Brasov, Romania, which studies the transfer of professional activity and organizational interaction into

online environments through the use of social networking. Also presented in this section is the chapter, **“Examination of Quality of Life in Workplace Environments,”** authored by Prof. Lesley Clack from the University of Georgia, United States, which breaks down the numerous factors that impact the quality of life of workers in healthcare, and provides effective management solutions to improve the overall well-being of medical professionals. One of the final chapters of this section, **“Leader Ambidexterity in Research Teams,”** authored by Prof. Montserrat Boronat-Navarro and Ms. María P. Mora-Crespo from Jaume I University, Spain, builds on organizational ambidexterity literature to determine the antecedents at the individual level of the main researcher to successfully achieve both research and commercialization activities. The authors review the ambidexterity literature to identify these antecedents and illustrate their framework with two research teams at different Spanish universities that have achieved scientific- and commercial-oriented results.

In summary, the authoritative contents included in this comprehensive reference publication is intended to provide a much better understanding of the issues, challenges, trends, solutions, and opportunities surrounding the themes of its fifteen sections; delivering thorough coverage of the most recent research conducted by various experts all over the world. Collectively, the authors of the chapters in this encyclopedia bring about the most current thoughtful and comprehensive overviews of many important topics related to organizational development and advancement in light of modern emerging technological innovations, providing a much better understanding of this particular area of research. We hope that their diverse and comprehensive coverage offered within their chapters will contribute to a broader awareness of all topics, research, discoveries, opportunities, and solutions in developing dynamic and progressive organizations that can survive and thrive in our modern competitive global economy with all its recent challenges. We are also hopeful that the contents of this publication will inspire other researchers to further explore the expansion of existing research to discover new ways of stretching beyond the current boundaries and identify new opportunities in the field that can be further developed to better serve the inhabitants of our planet and organizations worldwide.

Mehdi Khosrow-Pour

Editor-in-Chief

Encyclopedia of Organizational Knowledge, Administration, and Technology

User's Guide

The *Encyclopedia of Organizational Knowledge, Administration, and Technology (First Edition)* is a five-volume set comprised of 188 chapters. All chapters are divided into categories relevant to their topical coverage. There are fifteen different category sections, with each volume containing multiple categories. All category sections are arranged alphabetically across the five volumes. Within each category section, the chapters are arranged by their relevance to the theme and to each other. As each new category section is introduced, section dividers represent the transition from one category section to the next. Tabs on the right-hand side of each of the pages have numbers representing each corresponding category section number.

To assist with easy navigation, there are two different tables of contents compiled at the beginning of each volume. The first represents the “Contents by Volume,” which displays the arrangement of the content in its respective category sections, and the second represents the “Contents in Alphabetical Order,” which displays the arrangement of content from A to Z by the chapters’ titles.

EACH VOLUME CONTAINS

- A **preface and user’s guide**.
- The **Editor-in-Chief’s biography and acknowledgment**.
- **Two different tables of content** are compiled at the beginning of each volume: “Contents by Volume” and “Contents in Alphabetical Order.”
- **Several authoritative, research-based chapters** contributed by researchers and experts from all over the world.
- A **comprehensive index** supporting the extensive system of cross-references.

EACH CHAPTER INCLUDES

- A brief **introduction to the topic area** describing the general perspective and objectives of the chapter.
- A **background** providing the broad definitions and discussions of the topic and incorporating the views of others (i.e., a literature review) into the discussion to support, refute, or demonstrate the author’s position on the topic.

- Various perspectives examining the **issues, controversies, and problems** as they relate to the theme. Also provided are arguments supporting the position as well as a comparison and contrast with regards to what has been and/or is currently being done as it relates to the chapter's specific topic and the overall theme of the encyclopedia.
- A discussion of **solutions and recommendations** in dealing with the issues, controversies, or problems presented in the preceding section.
- **Charts, graphs, tables, and formulae** are included as illustrative examples whenever appropriate.
- A discussion of **future research directions**.
- A **conclusion** to discuss the overall coverage of the chapter and present concluding remarks.
- An extensive **list of references** so that readers can benefit from the sources cited within the text.
- An **additional reading section** consisting of sources that complement the topical coverage within the chapter.
- A **key terms and definitions section** providing 7-10 terms related to the topic of the chapter with a clear and concise definition for each term.

Acknowledgment

Editing and completing an authoritative and comprehensive scholarly research publication such as the five-volume *Encyclopedia of Organizational Knowledge, Administration, and Technologies (First Edition)* requires tremendous contributions and a great deal of assistance from large groups of scholars, researchers, and professional staff. The primary objective of this encyclopedia is to provide the most up-to-date scholarly coverage of all topics related to the conceptual, methodological, and technical aspects of organizational knowledge, management, and technologies.

The contributed chapters from expert researchers from all over the world provide an in-depth look into topics such as organizational structure, strategic leadership, information technology management, business analytics, corporate social responsibility, supply chain management, social networking, and much more. I am indebted to all the authors for their excellent contributions to this publication.

All submitted chapter manuscripts to this publication underwent a double-blind peer review process in order to achieve the highest level of validity, reliability, accuracy, and quality of the submitted research. I am thankful to all the reviewers of this encyclopedia for providing their expertise and their rigorous, unbiased assessment of the chapter manuscripts assigned to them on a double-blind basis, as well as the members of the Editorial Advisory Board for their wisdom, guidance, and assistance with various decisions throughout the editorial process.

I would also like to convey my deepest appreciation and gratitude to all those individuals who assisted me in editing this publication, which include Lindsay Wertman, Managing Director of IGI Global, Jan Travers, Director of Intellectual Property and Contracts at IGI Global, Melissa Wagner, Managing Editor of Acquisitions at IGI Global, Maria Rohde, Assistant Development Editor at IGI Global, Crystal Moyer, Assistant Development Editor at IGI Global, Eric Whalen, Assistant Development Editor at IGI Global, Josh Christ, Assistant Development Editor at IGI Global, Chris Shearer, Copy Editing Manager at IGI Global, Michael Brehm, Managing Editor of Book and Journal Production at IGI Global, and Deanna Zombro, Production Assistant at IGI Global. Additionally, I would like to thank the IGI Global Sales and Marketing Department, especially Nick Newcomer, Senior Director of Marketing and Sales at IGI Global, Caroline Campbell, Marketing Manager at IGI Global, Brittany Haynes, Marketing Editorial Assistant at IGI Global, and Tori Parks, Graphic Design Coordinator at IGI Global, for their endless support in promoting this invaluable reference source.

Thanks to everyone who has provided me immeasurable amounts of knowledge, wisdom, and support over the last 30 years.

About the Editor

Mehdi Khosrow-Pour, D.B.A., received his Doctorate in Business Administration from the Nova Southeastern University (Florida, USA). Dr. Khosrow-Pour taught undergraduate and graduate information system courses at the Pennsylvania State University – Harrisburg for almost 20 years. He is currently Executive Editor at IGI Global (www.igi-global.com). He also serves as Executive Director of the Information Resources Management Association (IRMA) (www.irma-international.org) and Executive Director of the World Forgotten Children Foundation (www.worldforgottenchildren.org). He is the author/editor of more than 100 books in information technology management. He is also currently the Editor-in-Chief of the *International Journal of E-Politics (IJEP)* and the *International Journal of Semiotics and Visual Rhetoric (IJSVR)*, and is also the founding Editor-in-Chief of the *Information Resources Management Journal (IRMJ)*, *Journal of Electronic Commerce in Organizations (JECO)*, *Journal of Cases on Information Technology (JCIT)*, and the *Journal of Information Technology Research (JITR)*, and has authored more than 50 articles published in various conference proceedings and scholarly journals.

INTRODUCTION

In a performance oriented time, organizational efficiency holds a primordial part, no matter what the sector of activity might be (Guo et al., 2017). One of the most important challenges is achieving it through developing and implementing performing management on a permanent basis (Wickramasinghe & Alawattage, 2007). Organizational efficiency has become an activity assessment management factor, bearing an important role in decision making in order to fully use the available resources (Gurd & Thorne, 2003).

A decision-making process taking place on various organizational, operational and strategic levels needs to rely on data regarding the costs borne as well as other reliable analyses from within the organization, supplied by a managerial accounting process which must provide answers to the information needs signaled by the management of that company (Chenhall & Langfield-Smith, 2003).

The role of managerial accounting consists in detailing, analyzing and interpreting the information provided by the general accounting, presenting it in a form that is accessible to the company management (Rowe, Birnberg & Shields, 2008). Financial information is confidential, addressed to the internal environment of the company, and presented as no standardized periodical reports adapted to the internal management needs (Abdel-Kader & Luther, 2008).

As a support for the managerial decision, managerial accounting information accompany the managerial process along its entire action flow: planning, the launching of new products or the creation of new activities, selecting clients or orders, substituting production factors, controlling the accounting management during all its stages (Baines & Langfield-Smith, 2003).

Romanian healthcare companies have stated that organizations have a problem with anticipating and adapting to what happens in their environments (Bostan, 2016). This inability to recognize changes in the

DOI: 10.4018/978-1-7998-3473-1.ch001

business environment can be a factor that determines the lack of performance in the field of competitiveness. To succeed, organizations need to adopt a systematic approach to change. In this respect, they will have to simultaneously manage all the challenges of change. These changes at the organizational level have increased the importance of managing change and especially managing the experience of change in personnel (Jung et al., 2016; Rojon et al., 2015; Schulz, 2004). This is due to the fact that major changes have an impact on all the members of the organization because these changes can create new dimensions of uncertainty. Only through a good knowledge of the entity, transparency of the management processes in order to increase healthcare service quality, diversification and the creation of internal mechanisms to respond to disruptive forces, can one ensure that companies remain in the market.

The concepts surrounding the organizational performance in health care organizations incorporate also the knowledge, skills and motivation of work force; factors that directly influence the service quality (Allen & Seaman, 2007).

It should be mentioned that traditionally, there exist differences between output and outcome. In our opinion, for the health care organizations the outputs (results) may be used as synonym for outcome (performance), because qualitative health care services may be delivered only under performance circumstances, which take into consideration the organization's efficiency and the level of patient satisfaction.

In the investigative approach to new change management challenges in the contemporary economy, we used a complex strategy of research, combining quantitative and qualitative methods of investigation. Therefore, specific methods were used in the preliminary stage of design and preparation of the research analysis, now presented as tables that allow optimal concentration of information. Any entity goes through processes of change and adaptation to changes in the business environment, which should be perceived, analyzed and evaluated by the management performance. All the scientific process involved taking into account all the parameters/variables considered useful in identifying the answer to the central research question. The entire research process involved completing specific rules, collection, analysis, and the selection of information that can be proven objectivity with a lot of rigor over a predetermined length of time. The results obtained are valid and reproducible because they are based on a methodology of well-chosen research that lends credibility to the conclusions we have reached at the end of the research period.

More importantly, the results of the present study suggest that a managerial accounting is important for the survival and success of any organization in today's business environment, which is extremely competitive and in a continuous evolution (Kemper et al., 2017). In the light of the apparent logical hole, the theories and approaches of managerial accounting that are available for theoreticians and practitioners often argue between themselves, and many of them lack the empirical evidence supported by incontestable hypotheses regarding the nature of contemporary organizational management of change (Hassan, 2005).

The rest of the article is organized as follows: first, we discuss the materials and methods development. Then, in Section 2, we present our results and discuss our findings. Finally, in Section 3, we provide the conclusion and suggest some future research directions.

BACKGROUND

The management of organizational change is a continuous process of experimentation and adaptation that has as its main target the correlation of capabilities of an organization to adapt to a volatile, changing environment (Gong et al., 2009; Popa, 2012). By the same token, Verbeeten (2010) saw organizational change as a transforming adaptive and complex change performed with the help of a system change

model composed from three stages: raising of the organization, the appearance of tension in the activity of the organization and a threshold, and the newly emerged configuration.

For a long time, the concept of organizational change has attracted the attention of both theoreticians and practitioners. Abernethy and Brownell (1999) claimed that in spite of the complexity of problems of change, and can be identified by the notion of transforming and the traditional dynamic inherent in the efforts for a successful change. Barnett and Carroll (1995) suggested that the fundamental changes in organizations can be classified into two major categories: changes in culture and changes in structure. Regarding the structural change in the organization, Fenton and Pettigrew (2000) studied the evolution of the theoretical concepts regarding organizations, from the bureaucratic organization (Dibrell & Miller, 2002) to the network organization (Hyvönen, 2007). However, Burns and Vaivio (2001) noted that the importance of change management can be better understood if it is regarded in the context of the expansion, shrinkage, and restructuring of the corporation.

In the studies regarding the management of change, the problem of resistance to change has always been considered an essential element of finding ways to obtain advanced management. Edwards (2010) argued that employees do not resist all change, only the changes that they do not understand or they see as a psychological or economic threat. As such, usually, they answer with adequate behaviors: dissatisfaction, frustration, confusion, and anxiety. The resistance to change can provoke the reduction of productivity, the slowdown of activity, hostility, and pessimism regarding the achieving of an aim. The causes are multiple: political, cultural, legal, and individual. In terms of understanding the notion of resistance to change, Lee, Yang and Chen (2016) stated that a person has to identify the factors underlying this resistance: self-interest, fear, peer pressure, and inertia. When leaders are able to pass on their values, the organization develops, and they are mastered and accepted by other employees as the right way to think and act. Piderit (2000) postulated that there are three different aspects of the conceptualization of resistance to change: as a cognitive state, as an emotional state, and as a behavior. In other words, the resistance to change is manifested both at an individual level and the level of the organization.

After examining the force of change and the possible resistance to change within an organization, formulating strategies of change is the next important step. Depending on the distribution of power in the organization, there are various ways to formulate strategies of change according to the size of the possible change and to the available time and information.

Accounting managers shall change the determination methods of costs when improve organizational performance takes place within a sanitary unit. To this end, the accounting manager is charged with further duties such as: to determine and register the cost of quality (Gerdin & Greve, 2004); to incorporate the quality cost in the account plan used (Chenhall, 2008); to develop the cost system which is based on the quality management (Andon, Baxter & Chua, 2007).

On the other hand, accounting managers must help the management team to use their capacities and skills in order to implement the organizations changes in the sanitary unit and more, to continuously improve quality (Choe, 2004). Including the organizations changes principles in the account management shall be done by supplying accountancy services afferent to the internal departments (Hassan, 2005), by identifying internal or external clients and satisfying the informational requests they have (Smith, 2003).

RESEARCH METHODOLOGY

Although there is in the specialty literature a degree of consensus regarding the relationship between management accounting and organizational change, few researches have been conducted regarding this

relationship in healthcare organizations in Romania. From this point of view, this work explores the relationship between management accounting and performance in healthcare organizations in Romania, using a questionnaire as a research tool.

The logical structure of the questionnaire allowed us to quantify each item from the process of implementation of change by subdividing the components and classification of variables according to the criterion of causality. To avoid reluctance from respondents in expressing their opinion, the evaluation of appreciation was done with the help of a Likert scale with five levels: strongly agree, agree, indifferent, disagree, and strongly disagree. All questions were closed-ended questions and was designed to cover two major areas within the conceptual model and developed hypotheses. The distribution and filling of the questionnaires were conducted from June 2017 to December 2017 in Romanian healthcare companies (MEDICOVER, Regina Maria, SANADOR, IOWEMED MEDICAL CENTER, MedLife, AMERICAN MEDICAL CENTER, POZIMED). To ensure the objectivity of the answers, the respondents were provided with a climate of anonymity.

The results of the analysis and interpretation of data will be done in two stages: the first step is to identify the strong and weak points of the management of change in Romanian healthcare companies from the perspective of the importance of management accounting practices in the success of change and the attitude toward change. The second step is to analyses and interpret, based on the statistical and econometric methods, the items for determining the management of change in Romanian healthcare organizations according to H_1 and H_2 .

Therefore, the following hypotheses are proposed:

H_1 : There is a significant positive interaction between management accounting information and performance

H_2 : There is a positive association between managing change in organizational development and increase organizational performance

In order to verify the hypothesis we used as statistical method the multivariate analysis. The analysis of variance MANOVA (multivariate analysis) is a technique used to compare the averages of two or more groups. Traditionally, the MANOVA technique is used to test differences between more than two groups, based on the linear combination of quantitative variables, while offering the possibility of multiple dependent variables (Grice & Iwaski, 2007). According to Table 1, by using Roy's Largest Root, one could identify a significant impact of the implementation month on the effects of the management accounting on the organizational performance and on patients' and human resources' satisfaction; this result allowing us to perform the MANOVA analysis.

Further, Table 2 highlights, that F statistic has an associated probability of less than 0.05 (Sig.<0.05), only for the first question regarding the effects of the organizational change on performance in a health care organization.

According to Table 2, although there exist significant differences only regarding the first dimension, one could identify differences between the dimensions referring to the effects of the organizational change implementation in health care organizations by comparing the means of each dimension associated with the month of implementation.

The other effects are not necessary related to the implementation month, but mainly to the health care organizations and refer to: the communication between the accounting department and other departments, the communication with the suppliers, the patient's satisfaction with the processes of diagnosis, treatment and procedures and the patient - doctor relationship (e.g. transparency and accuracy of information regarding diagnosis).

Table 1. Multivariate tests

	Effect	Value	F	Hypothesis df	Error df	Sig.	Partial Eta Squared
Intercept	Pillai's Trace	.997	908.373 ^a	10.000	29.000	.000	.997
	Wilks' Lambda	.003	908.373 ^a	10.000	29.000	.000	.997
	Hotelling's Trace	313.232	908.373 ^a	10.000	29.000	.000	.997
	Roy's Largest Root	313.232	908.373 ^a	10.000	29.000	.000	.997
Month	Pillai's Trace	.610	4.528 ^a	10.000	29.000	.001	.610
	Wilks' Lambda	.390	4.528 ^a	10.000	29.000	.001	.610
	Hotelling's Trace	1.561	4.528 ^a	10.000	29.000	.001	.610
	Roy's Largest Root	1.561	4.528 ^a	10.000	29.000	.001	.610

The authors found that 85.02% of the total number of all items were validated. Thus, all the hypotheses were validated, and there was no need to reformulate them. The findings point once again to the need for a model of change implementation in Romanian healthcare companies.

SOLUTIONS AND RECOMMENDATIONS

Inconsistency in institutional decision-making, continuous experimentation and the uncertainty in the public healthcare policies require quick and efficient alternative solutions such as: establishing multi-functional centers which should develop according to local needs and be supported by local communities and authorities, bringing together diverse medical specialists, community nurses, pharmacists, dentists, specialists in palliative care in home care, endowed with diagnosis and appropriate intervention equip-

Table 2. Test of Between – Subjects Effects

Source	Dependent Variable	Type III Sum of Squares	df	Mean Square	F	Sig.
Month	Total quality management	10.025	1	10.025	10.589	.002
	Operating income	4.602	1	4.602	5.239	.028

	Customer profitability analysis	.530	1	.530	2.042	.161

ment, as an alternative model to closing hospitals; hospital management should be done professionally, involving those who acknowledge the medical process, outside central or local political influences, by monitoring activity on the basis of credible and measurable indicators to eliminate arbitrariness in the assessment activity; development of services in one-day hospital admission system (chemotherapy, surgery day etc.); outsourcing some services only if they reduce costs, with verifiable quality conditions; hospitals subordinated to local authorities should be encouraged to associate to cost – efficiently acquire common services (laundry, catering, security, etc.); transferring certain care services for chronic patients (diabetes, hypertension, asthma) to outpatient hospital and primary care management through the development of integrated models of chronic patients; supporting private investment in new hospitals and facilities by state guaranteed loans and by partial support of interest loans; reviewing, completing and improving the legislation, especially on decentralization in the health system to avoid blockages and to allow adequate funding of services, cost control and effective decentralized management.

The management team has the obligation to create and supervise these processes and its success depends on the continuous improvement of services that ensures good management as well within the organization. This management philosophy aids the medical units to improve their performances by eliminating the poor quality of services and requires constant assessment and innovation within the organization. At the basis of this philosophy lie some techniques of settling the characteristics for the processes in progress within the organization, the monitoring of performances as compared with the characteristics, determination of the causes for inadequate variations (including the waste of quality and insuring productivity of employees, also settling the necessary environment for communication around the quality concepts and improving productivity.

FUTURE RESEARCH DIRECTIONS

In the next years, the authorities will manifest in a desire to accelerate change for Romanian healthcare companies to improve: managerial measures to strengthen the determining features to become dominant must be an objective, even if there are certain individual differences; these measures could include achieving knowledge that will complete the determining features of the strategy, and creating an inter-organizational coherence in which the customers, suppliers, distributors, and collaborators of the organization should be included; successive changes have to be managed through networking; complementarity, correlation, and implementation of the two main elements of each factor; the initial determining conditions; and the consecutive mechanisms empower Romanian healthcare companies to ensure their success in the market, which is an uncertain and consecutive process.

In any case, the leaders of the future need to understand the depth and impact of what managing change in organizational development means in their pursuit of performance, productivity growth, and selection and motivation of the human resource appropriate to the specific business.

CONCLUSION

The major problem healthcare systems today is the efficient management of the initiatives of strategic change, and the fundamental difference between successful organizations and those that fail is the ability to keep up with change (Briggs et al., 2012; Guillén & Saris, 2013; Pieper et al., 2017). In other words,

organizations in health system have to monitor and study external environments to anticipate and adapt quickly to change (Ericksen & Dyer, 2005; Meuer, 2017).

As long as the reality and the accuracy of the information supplied by managerial accounting are checked periodically, this guarantees the provision of good quality information to the management. This managerial accounting procedure is carried out primarily by comparing the expenses recorded by the general accounting with those recorded by the managerial accounting and incorporated in the marketing costs and prices, and by comparing the global results obtained according to the general accounting with the aggregate analytical results obtained based on the data recorded by the managerial accounting, and explaining the possible differences.

Using a qualitative model design, we demonstrate that no matter how well the strategies of change are formulated, the implementation of change is a decisive step in its successful realization. Managerial practice has shown that strategy implementation failure is the basic reason why people are anxious about organizational change. More specifically, the diversity of views expressed in the literature specifically referring to organizational change and management accounting practices helped us determine the best approach for positioning our scientific research on the new change management challenges in the contemporary economy.

Continuous quality improvement of a healthcare organization should focus on the following dimensions: cultural (emphasizing those aspirations, values, norms and behaviors that support or, on the contrary, are a barrier to the improvement process within the organization); technical (training in the use of tools or at least to be familiar with the group decision-making process in order to improve the quality of the organization's information system and data analysis capability); strategy (refers to the degree to which quality improvement efforts are focused on key strategic priorities and the strategic plan of the organization. At this level we look for answers to the following questions: Where does the organization want to reach? Is quality a priority?); structure (the presence of a coordinating committee, councils, working groups, existing mechanisms for reporting and analysis). This dimension binds all the others.

At the same time, the environment surrounding the transition to a market economy involves changes in the Romanian healthcare organization, changes that in turn affect the performance measurement system. Considering the current state of the relationship - strategy - organizational culture, the management tools that best meet the new challenges are reunited under the synergy of economic performance.

Each of us has the capacity to become a master of change. The paradigm is easily understood by those outside healthcare companies than by their members because the elements that compose self-explanatory are understood by itself. Managers receive a plurality of signals that are often contradictory and that they interpret through the paradigm. In this context, the paradigm is both an interpretation instrument and a formula of action, and Romanian healthcare companies use it to form their strategies.

In conclusion, one could admit that the implementation of a total quality management system has positive effects on the management accounting and on human resources' satisfaction. These effects are related on the hand to the cost structure and performance of health care organizations and on the other hand to the human resources' satisfaction and performance. It is important to note, that the patients' satisfaction and its' relationship with doctors are not necessary related to the quality management system, but rather to the organizations' politics and structure. However, the implementation of a quality management system is a strategic decision in order to standardize all the organizational processes and their better management in a health care organization and is based on principles that refer to: continuous improvement and alignment between process goals, customer goals and process management.

KEY TERMS AND DEFINITIONS

Budget Accounting Management: Related not only to the accounting activity but is a true company administration technique, a company management philosophy involving three stages: estimation, budgeting, and control.

Cost: The money form of all material and labor expenses made by the company to produce and market material goods, execution works and service works.

Decision: A person or group of persons' social and deliberate act defining the purpose and the objectives of a certain action, the directions and the ways to achieve that action, all of them determined, according to a certain need, by a process of obtaining information, deliberation, and assessment of the means and consequences of carrying out that action.

Economic Management: The achievement of the budget objectives with minimum costs so that when the activity is completed the revenue exceeds the costs, namely there is a profit that ensures a level of profitability as high as possible both at general level and by product, department or service performed.

Financial Management: A tool in the decision-making relating to the collection and analysis of information in order to increase the performance level of the economic entity.

Managerial Dashboard: Contains a set of actual information presented in a predetermined form, relating to the main results of the company's activities or to some of them and to the main factors conditioning their effective and efficient progress.

Organization: A system, which includes employers and employees aiming at achieving common objectives.

The Potential Role of Intellectual Capital in the Process of Accounting Convergence

Ionica Oncioiu

Titu Maiorescu University, Romania

INTRODUCTION

The value of intangible assets has been the main focus in the debates between international professionals and business world for many decades (Chen, Qu & Sun, 2017). Today, this concept interferes with the international process of assessment, but also with the convergence of accounting (Englund & Gerdin, 2018). The need to determine the value of these assets lies in the more virulent criticism brought to the traditional accounting system, placed face to face with an increasing vision of the financial assets of a company (Anson, 2008). In an uncertain world with imperfect and incomplete markets (financial crisis), no particular measurement objective should be regarded as having a monopoly, and different measurements should be regarded as complementing one another (Florou & Pope, 2012).

The problem is how to choose the best of them in the context of satisfying the requirements of the accounting information users, on the one hand, and complying with accounting principles and fundamentals, on the other (Vladu, Amat & Cuzdriorean, 2016).

Basically, because of different research directions, confusion can arise regarding the use of the following terms: intellectual capital, intangible assets, and knowledge assets. Thus, the term “intangible assets” is used especially in financial accounting, in the active knowledge economy and also the term “intellectual capital / human capital management” is being used particularly (Guthrie & Dumay, 2015).

Recently a number of classifications have refined the distinction between intangible and intellectual capital, separating the latter into several components (Matricano, 2016; Abeysekera, 2006): customer-related capital (external) structural human capital (internal).

It has been shown that various components of intangible values do not only have different significance, but they also have a complex interdependence and influence each other constantly. This makes it extremely difficult to evaluate each component separately. The view that each component of intangible values can be managed separately, without taking into account synergies, is both theoretically and practically wrong, while being legally and practically not feasible (Andreou, Green & Stankosky, 2007).

Meanwhile, the home values’ intangible image shows very clearly why it is less profitable as a company to worry about capital intensive innovation and capital investment, as long as there are significant deficiencies in the management of subordinate components. In this respect, the individual components are difficult, exclusive, and do not adequately reflect the overall context of the components and their cause-effect relationships (Abernethy, Bianchi, Labory, Lev, Wyatt & Zambon, 2003).

Accounting estimates of intangible assets being made by the management entity are a risk in the sense that they may not be correct, so we have to analyze and better understand the assumptions used for this purpose, to pursue compliance with the accounting standards and the concrete conditions of their application (Ball, Li & Shivakumar, 2015). Equally it is necessary to identify the real purpose of these accounting estimates, so that they ensure the credibility of the beneficiary’s recognition, measurement and disclosure of intangible value.

DOI: 10.4018/978-1-7998-3473-1.ch002

Accountants, in their turn, reflect accounting estimates only in registers and certainly not at the value generated by the presentation of materials. There is a clear dichotomy between the historical cost accounting and fair value in accounting measurement, which creates a productive tension in discussions related to economy based on knowledge. However, it is more likely for a certain period of time to develop both paradigms in parallel and then become convergent, thus solving the paradox of intangible asset valuation.

BACKGROUND

In recent decades, in Europe and the United States, each intangible accounting entity leads under national laws and regulations for each country in which that entity operates (legal personality, subsidiaries and branches). In situations where time was written in a book on the situation of an entity, the assets of a European state established after that state's laws and regulations operate outside the legislation of other European countries or even overseas (Li, Qi, Tian & Zhang, 2017).

To overcome such problems, we should recognize internationally intangible assets at the end of each accounting year, their transparency, as well as prevent fraud and the violations of accounting principles, to help business people (investors) contribute to the Council of Europe (CoE), which brought changes in the accounting rules (national, European, and international) and contributed to the adoption of certain international accounting standards. These include accounting regulations which facilitate the investors' desire to expand business in other countries since before the adoption of IFRS; there were situations in which a U.S. investor wanted to open a business in a country in Europe or Asia and did not fail because of the existing accounting legislation in that country (Ahmed, Neel & Wang, 2013). These standards have been accepted by the European Parliament and the Council of Europe, thus creating the IFRS (International Financial Reporting Standards). By developing IFRS, the Council's objective was to find appropriate solutions to any entity anywhere in the world.

Also, many economists have stressed the importance of intellectual capital as a production factor in comparison with traditional assets (Cerbioni & Parbonetti, 2007; Alstete & Beutell, 2018). There are two theories on economic growth: the theory of neo-classical growth and the theory of exogenous and endogenous growth. Intangibles reflect different endogenous models (Braam & Nijssen, 2001).

According to the endogenous growth model, production is defined as a function dependent on the accumulation of immaterial (intangible). Over time, permanent growth is possible only if the intangible capital stock changes virtually forever. As a management problem, the intangible asset is not new, but the problem of "intellectual capital" is the last line developed in the knowledge management.

The Norwegian Government has funded a research project to develop a model of skill capital of the company, he was later involved in an ISO-type certification process that included intellectual capital.

In all these experimental projects prevailing the spirit of participation rather than a theoretical development, the current area of interest in intellectual capital research includes: the creation and management of intellectual capital, understanding how to best measure intellectual capital (Anson, 2008).

Cravera, Maglione and Ruggieri (2001) indicate that "the scientific literature and official texts do not have clear definitions for the notion of intangible asset. Most authors prefer to make a simple list of all the main components while accounting official texts in order to define this vague notion. In fact, the general definitions quickly become useless due to their very little analytical and more precise definitions prove to be too limited to particular cases".

Regarding the practical need of these measurements it can be supported by an international study on measuring the importance of intellectual capital in the businesses, led by Arthur Andersen in 1998

and held within the 368 companies in Europe, North America and Asia (Martory & Verdier, 2000). The results of this study can be summarized as follows:

- The majority of respondents are convinced that reports on intellectual capital will increase quantitatively;
- Almost three quarters of respondents have already tried the organizations they lead, at least two non-financial measurement models;
- The majority believes that the assessment firm's intellectual capital can be increased based on organizational performance;

Similar studies have been done so in 1998 a study conducted by Watherhouse and Svendsen (Measuring What People Know) and conducted on a sample of 114 top managers of the largest Canadian companies found that measuring intellectual capital is considered as a basic strategic condition and the company's management should constantly reported, as often as other non-financial measurements such as innovation, product quality, customer relationships with investors and business partners, community relations, the effects company activities on the environment (Lev,2001). Of all these non-financial measurements, the respondents were considered the least satisfied in terms of indicators that capture the firm's intellectual capital.

However, in the '90s, new methodologies for measuring expression and intellectual capital have been developed and applied, such as "Value Platform" – developed by Dow Chemical – "Intangible Assets Monitor" from Celemi, "Value Scheme" from Skandia, etc.(Lynn, 1999)

According to Sveiby (2010) a variety of metrics have been created to try to evaluate levels of intellectual capital in firms, both bottom-up (assessing individual employee knowledge and adding it all up) and top-down (calculating intangible assets as a remainder from financial statements). Preferences vary, but just note that measurement is a topic that has been explored in some depth and that dozens of potential choices are available to firms looking to evaluate and then better manage their own intellectual capital (Kwansa, Mayo & Demirciftci, 2008).

In general these models support the idea that intellectual capital components can be summarized in three groups: human capital, organizational capital and customer capital generated, the goal being to maximize the value of the company. A new emerging research trend seeks to apply the concept of intellectual capital to the field of entrepreneurship (Matricano, 2016).

CHALLENGES ACCOUNTING FOR INTELLECTUAL CAPITAL: STAKES, ADVANTAGES AND LIMITS

Intellectual capital, measured by education and training at work, he has developed (Roos, Roos, Dragonetti & Edvinsson, 1997). This happened the importance of intangible assets for the success of companies has increased significantly and traditional economic concepts and management proved not to be adequate. Thus, the latest economic and management studies have focused on developing tools to facilitate a better understanding and representation of intangible (Doppegieter & Zoller, 2008; Barth, Landsman, Young & Zhuang, 2014).

The main issue in terms of measuring systems is that it is not possible to measure social phenomena with scientific precision. Thus it tends, in the absence of appropriate tools to use traditional methods

based on the figures - financial indicators or remove the real cause of the phenomenon that caused the occurrence of these intangible assets.

Measure aims to discover opportunities for cost or value creation, which are otherwise hidden in traditional accounts. How much does the replacement of staff? What is the lesson learned when company staff interaction occurs with customers? What is the lost opportunity to create value where there is inadequate management systems knowledge? These are some questions to answer which is given by measuring intangible.

To meet new challenges, many companies, especially in Northern European countries, have focused attention on the concept of intellectual capital and the adoption of tools for classification and identification of new determinants of value (Campisi, 2006). Accordingly, they began to be used and linguistic terms such as “Intangibles Report” or “Intellectual Capital Report” (designate different models of identification and presentation of intangible assets).

Frustrations expressed by the studies mentioned on the measurement of intellectual capital are interesting and suggest, on the one hand, the need for tangible measurement of intangible assets in general and particularly intellectual capital, and on the other hand, that the attempt has been made now leaves room for improvement (Andriessen & Stam, 2004).

Considers that, before presenting in detail the different methods of reporting and measuring intangible are used so far, it is necessary to present a general classification will serve as a basis for analysis and will facility understanding of the specificity of each method (Sveiby, 2010). Sveiby proposed classification is presented in 2001 and is based primarily on the dichotomy that characterizes these methods and models: orientation atomistic/holistic orientation (e.g., models that measure and/or individual is intangible that models that measure and/or is intangibles overall available to organizations). Then, starting from this basic distinction is a distinction between methods of monetary and non-monetary:

- *Monetary methods are useful in mergers, acquisitions of new companies listing on stock exchanges*, comparisons made between companies in the same field of activity, moreover, the methods money have been developed based on accepted accounting rules so that they can be easily learned by accountants;
- *Non-monetary methods is the determination of innovation and performance management company* also may be noted that these methods have the advantage that it does not express the intangible assets in financial terms, so that they can be applied at any level of organization in non-profit, public companies, and/or organizations with social objectives.

According to these differences, results in a matrix with four categories of methods:

- *Cell A. – holistic and monetary methods*: A method includes using financial models and, on the one hand provides a general representation of the intellectual capital of organization supporting a determination of their money and, on the other hand, because of the nature their very general and brief no intangible enable administration for the purposes of creating value.
- *B cell - atomistic and monetary methods*: using monetary methods include but are applied to individual intangible assets. However, although these methods focus on individual assets do not provide a clear vision of the organization in total intangible assets of total assets.
- *Cell C - atomistic and non-monetary methods*: includes non-monetary atomistic methods, among them, being found most important innovations thousand and more in line with the “atmosphere” knowledge economy. But, and this presents some weaknesses, namely that it does not allow com-

parisons and that are not always able to accurately reflect the value of individual intangible assets and, therefore, often based on approximations.

- *Cell D - holistic methods, non-monetary*: it is observed that the literature does not provide such methods of measurement yet eloquent.

Another classification of the methods used so far was made all the Sveiby (2010), based on ideas suggested by Epingard (1999), is as follows:

- Direct assessment of intellectual capital methods (DIC). Estimating the value in cash of intangible assets by determining the various components. After these components are identified, they can be measured directly, either individually or with a compound coefficient.
- Market capitalization methods (MCM). Calculate the difference between a company's market capitalization and shareholder equity value as the value of its intellectual capital or intangible assets.
- Method returns on assets (ROA). Average pre-tax earnings of a company for a period of time are divided by average assets of the company's tangible. The result is ROA - return on assets of the company which then compares the average of its industry. The differences multiplied by the average of tangible assets of the company to calculate the average annual earnings from intangibles. Dividing the average earnings above the cost average capital company or the interest rate, you can estimate the value of intangible assets or intellectual capital thereof.
- Method scores (Scorecard - SC). Establish various components of intangible assets or intellectual capital and generate indicators or indices that are reported as scores (scorecards) or graphics. These methods are similar methods in that DIC is based on identifying components of intangible assets, but unlike, they do not consider the need for a financial estimate of the value of intangible assets.

Methods offer different advantages (Bontis, Dragonetti, Jacobsen & Roos, 1999). Thus the actual amount that provides evaluations (\$), such as ROA and MCM, are useful in cases of merger and acquisition and stock assessments. May be used to compare companies within the same industry and are useful to illustrate the financial value of intangible assets, feature that tends to draw attention to managers. Because they are based on counting rules long established and recognized them in different national laws or regulations can be easily communicated to the accounting profession. The disadvantage is the fact that all the terms, making money, they can be superficial (Li, Qi, Tian & Zhang, 2017).

DIC and SC methods advantages are that it can create a more complex organization in terms of health than financial metrics and ROA and MCM can be applied easily to any level of organization (Kaplan & Norton, 1992). Measurement is made closer to the event and so reporting can be more accurate and faster than financial measurements. Their disadvantage is that the indicators are contextual and must be adapted to each organization and each objective, which makes comparison difficult. Also, the methods are new and are not easily accepted by the companies and managers who are accustomed to seeing it only in purely financial.

From the perspective of global experience in evaluating intangibles, we can remember the following methods:

- Skandia Navigator, is probably the most well-known and analyzed intellectual capital measurement model that literature offers to date. Thanks to its innovative qualities it is considered a kind of archetype for the class of models for non-monetary atomist measuring. Among the advantages

of this model are: it initiated a series of efforts toward abandoning traditional ideas about the determinants of value in organizations and bringing to the fore the possibility of measuring intangible assets; it highlights the crucial role of customer relationships in business value creation and shows how the nature of the relationship between companies and their customers changed; for the first time a great importance is attached to the contribution that can bring renewal and development of the organization's value;

- the Intangible Assets Monitor is a model that can be applied to all companies and its indicators are chosen according to the characteristics of the company, industry, competitive variables, company's history, organizational culture and company management. According to the model, intangible income can be divided into: strengthening the company's image, strengthening the organization and enhancing its competence;
- the Balanced Scorecard model that Kaplan and Norton have designed does not present a general system of indicators to measure intellectual capital, the argument being that a general system of indicators could leave out certain aspects of each company related to its objectives, processes and the context in which it operates. Traditional indicators provide information about the past performance of the company, while non-financial indicators can measure, for example, customer satisfaction, corporate innovative activities and improvements to various processes of the company. Combining the two types of indicators allows managers to obtain a balanced image on company performance. Braam and Nijssen (2001) point out that diffusion of innovative practices of management or management accounting, such as the Balanced Scorecard, can bring a discrepancy between the "tag" of the implemented concept and its contents. Authors such as Guthrie and Dumay (2015) have shown that this model can be used for evaluating intellectual capital. Comparison made between Balance Scorecard and intellectual capital valuation methods reveal other similarities such as recognition strategy as an essential component of performance management need to find a concise and fully expressing the company's situation, attention to intangible assets and knowledge. In other words, it is possible that some organizations only claim that they use the Balanced Scorecard, while the implementation substance ignores the considered defining characteristics of Balanced Scorecard (connecting indicators to the strategy, causal relationships between indicators etc.). Therefore, to assess whether the Balanced Scorecard is used in practice is dependent on defining and clarifying the concept, ie the unequivocal identification of the characteristics that define a Balanced Scorecard;
- Lev's Knowledge Capital Formula Method for measuring knowledge capital is based on the traditional method for calculating goodwill. One difference is that, in Lev's model, additional revenues are replaced by residual income attributable to intangible assets. Based on these critical observations, in the scientific literature, the Value Chain Scoreboard has appeared, which is an atomistic method of measuring intangible assets which are pending completion;
- Criticism of the method Tobin's Q considered the volatility of the courses on the capital market, often beyond the control of management, which directly affect the market value of the intellectual capital of the company, and focused on the fact that this way of calculating the intellectual capital is not very robust. However, in his work, Stewart argues, by exemplifying, that both market value and book value may be diminished. Another weakness of the method is that the indicator "Q" may not be determined by the value of intangible assets;
- the Economic Value Added model was initially developed as an internal measure of performance used by managers to help them make decisions on investments. In practice, it has been demon-

strated that an investment project which causes higher income than the net cost of its funding and thus generates profit, does not necessarily lead to an increased company value;

- Technology Broker stated that it is itself an intellectual asset for organizations. But the main weakness of the model is considered to be related to the possibility of transforming the qualitative results in monetary results. For example, using market-based approach is likely to not be identified on the market any information on prices of many of the elements that form the intellectual capital. Income-based approach suffers from the bias of the estimates cash-flow;
- the Weighted Patents Citation model estimates a “technological factor” to identify the impact of research-development efforts leading to the creation of intellectual property and uses indicators such as research-development expenses / sales, number of patents, income / research-development expenses, etc. “The evaluation process of patents” is an effort that involves teamwork, in which specialists interact in marketing and research-development to decide the viability of abandoning or continuing the research-development process;
- being the world’s second-best managerial methods used by a leader in the process of organizational change in 2015, aiming to increase the performance of the entity, Benchmarking’s impact on the era of digitization promises to deliver concrete solutions to the challenges turbulent environment.

Based on this overview of the different methods of measuring intellectual capital of companies, we can say that the literature and practice offer several models, each with its strengths and weaknesses (Ahmed, Neel & Wang, 2013). Moreover, we can see that some of the intellectual capital valuation models are built on the same principles and using the same indicators, but they are named differently. For example, Skandia Navigator uses the term “human capital”, Technology Broker uses the name “people-based activities” (human-centered assets) and Intangible Assets Monitor uses “staff competence” to denote the same concept.

Andriessen and Stam (2004) on the other hand, have introduced significant changes, particularly with respect to organization. They break down each of the other IC groups between assets, investments, and effects. This approach is intuitively appealing as it provides a reading on the current stock of intellectual capital, its impact, and its potential for the future.

There are other versions, some adding categories, but most scholars stick with the three basic categories (and virtually all research includes the three in some form) (e.g. Andreou et al., 2007). If knowledge assets are the single most valuable asset available to a firm seeking to establish sustainable competitive advantage in the marketplace, per the resource-based/knowledge-based theory of the firm, there are clear implications for corporate governance. As a result, at the intersection of intellectual capital and corporate governance is an interest in disclosure. The art of managing knowledge assets is complex and, as previously noted, the payoff may be long in coming and difficult to tie directly to investment in knowledge. While the specifics disclosure are still early in development (Abeysekera, 2006), there have been some moves toward standardization. Managers recognize the value of showing investment and interest in developing intangibles, and voluntary disclosure rectifies issues such as information agency (Kwansa, Mayo & Demirciftci, 2008). Guthrie and Dumay (2015) reveals that interest in public sector and IC is alive and well and the major difference between public sector and mainstream IC research is a complete lack of normative research.

This demonstrates that the field is still at an early stage and no one wants to give up their own nomenclature borrowing aspects of the work of others, as long as it was shown that one method is generally valid. For this reason, an important aspect of research is to develop a common set of definitions and indicators that can be easily generalized.

An optimistic attitude regarding the chances of success of a development project will lead to the capitalization of development costs, with implications for the size of the result, the capitalization for the year (Florou & Pope, 2012). In future exercises, expenses recording with amortization will impact the result in the sense of decreasing it. If the enterprise has the interest payment of development costs in the profit and loss (expenditure) it will claim that at least one of the conditions stipulated by IAS 38 para. 43 is not met.

One criticism of the procedures above concerns that they contain a certain „dose” of creative accounting with the character of subjectivity with the realization that they change the presentation of accounts, but are nonetheless the result of an option, when selected from among more methods, which makes us say that they are within the accounting regulations (Chen, Qu & Sun, 2017).

Referring to development costs, for example, their positioning on the boundary between evaluation and accountability requires the existence of a bias caused by handling interest income. If the enterprise has a policy aimed at transferring these expenses in the profit and loss (expenditure) account, we can claim that at least one of the requirements for classification as an intangible asset development costs - which would affect the balance - is not met.

The Fourth Directive states that these expenses must be charged to the profit and loss, unless national law does not provide for their capitalization (Anson, 2008). These provisions were acquired differently by the EU countries, in Germany is forbidden to capitalize these expenses. France is the opposite, considering them capitalizable and depreciable in 5 years. In Belgium, Italy and the Netherlands, the capitalization of the costs of research is questionable, the trend being the exclusion of these expenses from the asset (Ball Li & Shivakumar, 2015). Development costs can both be capitalized and amortized within 5 years (Belgium and Italy) or during their useful life (the Netherlands). In Spain and the UK, research costs are non-capitalizable under certain conditions and can be amortized for a period of 5 years, respectively during the useful life.

All the measures against „fraudulent” accounting practices must have the purpose to ensure a capital accounting information on qualitative intellectual capital that faithfully represents reality and to allow decisions to ensure an optimal allocation between participants in value creation (Vladu, Amat & Cuzdriorean, 2016).

Prior to the introduction of the International Accounting Standards (IAS), asset valuation occurred at a historical cost reduced by the depreciation value at the time of the valuation, which did not always provide a fair value of those assets due to the impossibility to define a useful value for the exact use for each asset. Another method previously used was the valuation of assets based on the replacement value, which did not offer a fair value because of the difficulty of identifying accurate replacement values. Whether the valuation could be made at a historical cost or replacement value, this involved the use of professional judgment and estimates. These were the prerequisites for introducing fair value as the basis of assessment in the IAS.

The purpose of introducing fair value was to provide a fair representation of the amount of assets and liabilities of an entity presented in the financial statements that may be obtained if those assets or liabilities were disposed of at the preparation time of the financial statements. According to the fair value measurement, the most important component of the financial statements is the Balance Sheet. According to the recent studies, the use of fair value favors a realistic approach in favor of previous conservative approaches (Ball, Li & Shivakumar, 2015; Florou & Pope, 2012). At present, the fair value is the most popular method used among all permitted evaluation methods, but it still has a major disadvantage, namely subjectivity. Another disadvantage of using fair value is the lack of tools to verify it. Furthermore, it is still permitted to use the historical cost method as a fair value, which can lead to a significant distortion

of the results (Chen, Qu & Sun, 2017). Even if fair value is aimed at improving the balance sheet value measurement tools and reflecting a relevant and current business valuation, it is the engine for creating prerequisites for creative accounting, especially with regard to asset valuation.

FUTURE RESEARCH DIRECTIONS

Therefore, their representation in situations of intellectual capital value as intangible asset, to a value as close as possible to the real one, is essential for users since they ground their decisions based on its level (Matricano, 2016).

Moreover, the success of any company depends not least on whether the intellectual capital has recognized the important role of an examination over several years of the development of intangible values both in the construction of the house of intangible values and the annual evaluation, and if it has implemented this knowledge consistently in everyday decisions.

The main controversy raised by the aforementioned standards refers to the need for periodic reassessments and the possibility of choosing a method of measuring the value of assets, which creates premises for the practice of creative accounting (Englund & Gerdin, 2018; Guthrie & Dumay, 2015).

Regarding the revaluation of assets, the standards specify that if a revaluation of an asset of a particular class occurs, all assets belonging to that class need to be reassessed, which can lead to high costs for the entities.

The permissiveness of choice between two valuation methods is also regarded as confusing and unreliable, which may have an adverse effect on the objective of providing a basis for the comparisons between entities. The reliability of the information from an investor's perspective is also low due to fluctuations in the value of an investment portfolio.

The author believes that due to the high influence, both positively and negatively, of the intellectual capital on its value is necessary for conducting more detailed studies of diagnostic analysis to identify and measure them, and also to determine a set of evaluation methods that leads to a correct result, close to the market.

Of course, the appeal to intangible resources in order to create value remains a significant challenge for specialists because the country's competitive advantage should be interpreted in relation to the skills, talent and intellectual capital stock. Future research efforts of SMEs should turn those scales into operational parameters and promote the development of empirical methodological studies based on dialogue and the dissemination of knowledge and experience in interdisciplinary research teams.

CONCLUSION

Each company has its unique set of knowledge, skills, values and solutions, all intangible resources. Monitoring and management of these resources can be made with value creation efficiency analysis because it is a priority for managers to obtain and maintain productivity and efficiency in the enterprise.

Another aspect that can be observed is related to the fact that some researchers have developed theories based on reflection the results of case studies, others have developed some indicators that have applied in practice (as in the case of Skandia, for example) but without testing their validity in advance and others have developed sets of indicators were not tested. For this reason another challenge in the study of intellectual capital is the need for researchers to base their conclusions on several empirical

researches. And, to make conclusive statements about intellectual capital, we need to consider that a coherent field theory has positive effects in multiple areas such as accounting, human resources, finance, strategic management, etc.

Very important is that those who investigate aspects of intellectual capital to set realistic goals. As with many challenges, such as efforts to conceptualization of the field, trying to measure intellectual capital; setting causal relations - effect, demonstrating the accuracy of proxies, it happens that many companies have an intellectual capital management system its use in some individual indicators whose relevance is not fully justified.

It is therefore important to determine and establish relevant indicators, the group of them in specific categories (quantitative or qualitative aspects related to individual company's business - e.g. employees - or macro issues) and not I just put together, and also to assign each category a specific weight in calculating the final result.

KEY TERMS AND DEFINITIONS

Assets: As future economic benefits controlled by a particular business entity and also as economic resources which are owned by a business.

Estimate: Opinion regarding the value.

Financial Accounting Standards Board (FASB): Set up and develop generally accepted accounting principles.

Intangible: Represent immaterial assets.

Organizational Performance: Elements affecting company performance such as financial and marketing factors, return on sales, return on investment, etc.

Valuation: The process of determining the value of an asset.

Manipulating Business Performances by Creative Accounting

INTRODUCTION

The manipulation of accounting values or the practice of creative accounting is possible due to the gaps in the accounting regulations and due to the freedom to choose and decide between the accounting methods allowed for the treatment of different categories of balance sheet items or the profit and loss account. The risk of misrepresentation of results is not an easy to measure risk, which makes it difficult to compare the results of entities in the same industry or to perform other financial analyzes (Akpanuko & Umoren, 2018).

On the other hand, the interests determined by factors such as intensity of competition or increased pressure on businesses to communicate the „digestible” results, especially from investors and analysts, make the information collected by market valuation experts and accountants mitigate the possible effects of creativity (Chen, Qu & Sun, 2017). If the purpose of creative accounting is to improve the accounts (or the image created for the company), taking advantage of the weaknesses and deficiencies of accounting regulation, the authors consider that this concept is nothing new, because the principle of accounting options has been known for a long time (Holthausen & Watts, 2001; Baker & Bettner, 1997; Caylor, 2010).

The emergence of creative accounting was influenced by the flexibility of international accounting rules (Damayant, 2013). Creative accounting is treated in most cases negatively (negative creation), designed to lead to achieving value for intangible assets able to respond to the wishes of managers on the company's financial position and performance (Doukakis, 2014). Simultaneous treatment of creative accounting as a tool to achieve the interests of accounting and accounting engineering is based on the accounting policies adopted by a patrimonial entity to produce and communicate information (Richardson, 2011; Jackson & Liu, 2010; Ball, Li & Shivakumar, 2015).

Accountants who accept the ethic challenge of creative accounting should be aware of the abuse to both the choice of accounting policies and to the handling of transactions (Byard, Li & Yu, 2011). Such accounting has developed mainly in Anglo-Saxon economies due to the freedom of the accounting profession. It was placed on the edge of the legal form and economic substance of transactions and events (Barth et al., 2014). Discussed in terms of accounting practitioners, creative accounting has facilitated the emergence of basic and alternative treatments used to solve problems (Ahmed, Neel & Wang, 2013; Barth, Landsman & Lang, 2008; Fan, Li & Zheng, 2016). Of course, issues of evaluation of assets are cases of creative accounting practice that involve subjective reasoning as it applies to the professional

DOI: 10.4018/978-1-7998-3473-1.ch003

accountant or expert appraiser. Using creative accounting for intangible assets, for example, especially in its gray area favored by accounting rules, makes it difficult or even impossible to guess the true value of these assets (Li, 2010; Ozkan, Singer & You, 2012; Barth, 2013).

In this context, the following questions arise: will we return to accounting at the initial cost, in which intangible assets are recorded at outdated values and are therefore not relevant or reliable? How important are the psychological factors in accounting measurement? Can a model of assessment ensure the maximum quality of the accounting information on intangible assets? The answer to these questions, as well as various controversial issues of the fair value concept of intangible assets, are presented in the current draft of the International Accounting Standards Board (IASB) and the American Accounting Standards Board (FASB). As a result, today, we perceive an accelerated rate of change, aggressive disruptive phenomena and emerging economies that are rapidly developing against the backdrop of a Digital Era (Chen et al., 2010; He, Pan & Tian, 2017).

BACKGROUND

The foundation of creative accounting is therefore the manipulation of the accounts by the voluntary increase or decrease of the accounting values recorded in them (Heald & Hodges, 2018). From the perspective of the existing risks, the actions of manipulation of the amounts recorded in the accounting accounts are influenced by the systematic and financial risk (Fan, Li & Zheng, 2016).

Even though the definition of creative accounting is not unique, all definitions have as main elements the use of knowledge and skills of accountants to manipulate results with the deficiencies existing in legislative normalization systems.

Moreover, theme creative accounting practices are addressed by several disciplines: accounting, information technology, psychology and management, but they have grown tremendously in recent decades throughout the entire spectrum of companies (Brown, 2010). Creative accounting is operating at shade where accusations substantiated by non-compliance with professional or legal norms can be brought, but where common sense logic notifies the presence of a certain dose of „forcing the note” (Bettner & Kate, 2013).

Entities may use creative accounting tools when listing stocks on their stock market and aiming towards maintaining a stable course of shares when there is an increased volatility in financial and capital markets, which creates a high economic and financial risk when the field of the economic operations is multinational and several regulatory bases are needed to work in harmonization, etc. (Ball, Li & Shivakumar, 2015) These are examples of practicing “positive” creative accounting, but given the very small boundary between the positive and negative nature of using the creative accounting tools, the examples mentioned above can lead to fraud and tax evasion.

From the managers’ perspective, there are several reasons behind their decision to practice creative accounting, namely: reaching internal targets, reaching expectations from the external environment, smoothing or standardizing incomes to provide a steady image of the performance, facilitating the conduct of takeover bids or contracting loans, reducing tax obligations, changes in management.

A number of authors have described creative accounting as such:

Parker notices that ‘all businesses hide their benefits. The published synthesis documents are based on registers that have been ‘delicately’ or even substantially altered. The figures presented to the investors have been entirely changed to protect those guilty. This is, in fact, a legitimate scam and is called creative accounting...’ (Parker, 2012). The practitioner, Ball, states that ‘the accounting process involves

operating with different opinions and resolving conflicts between them in order to present the results generated by transactions. Such flexibility facilitates manipulation, deception and distortion. These activities, practiced by some less scrupulous members of the profession, are becoming known as creative accounting... Creative accounting does not violate law and accounting rules. It respects the letter, but obviously not its spirit... There is no doubt about the negative nature of creative accounting. It distorts the results and the financial position of the enterprise, and if we lend credence to the theoreticians, it becomes an increasingly used practice...' (Ball, 2013). Lukka defines creative accounting as a communication technique that aims to improve the information provided to investors (Lukka, 2010). On the same line, Dennis believes that the creative accounting expression describes 'accounting practices, often at the limit of legality, practiced by some businesses that, taking advantage of the normalization limits, seek to embellish their financial position image and economic and financial performance' (Dennis, 2014).

The different methods of recording intangibles through creative accounting can be classified into four categories (Schleicher, Tahoun & Walker, 2010):

- Sometimes accounting rules allow a company to choose between different accounting methods. For example, a company can choose the accounting policy which gives the desired image (it is allowed to choose between treating development costs as expenses when incurred, or to absorb these costs throughout the project life);
- Some accounts of intangible assets involve a degree of estimation, reasoning and prediction, especially when there is no market for that asset. These estimates are usually made in the company or by an expert evaluator and the creative accountant is able to assume a position of caution and optimism in setting the estimate;
- Artificial transactions can be recorded to manipulate intangible amounts on the balance sheet and to transfer profits between accounting periods (sale and lease-back);
- And real transactions involving intangibles can be planned at various times in order to create the desired impression to accounting information users. Property entity management is free to choose the year when they will sell the intangible investment, increasing the profit in the financial statements.

The methods in which some processes reveal creative accounting for intangible assets can be grouped in:

- Processes which have the effect of modeling the result and management decisions;
- Processes and techniques meant to improve the effect of balance sheet information;
- Processes which impact the presentation of the results.

Besides, International Financial Reporting Standards have been introduced to facilitate the understanding of financial statements and to provide increased transparency but also to limit the possible opportunities offered by a creative accounting (Ozkan, Singer & You, 2012). While the purpose of the standards has been to protect all stakeholders by providing relevant, neutral, credible and verifiable information, certain irregularities are still likely to occur, in particular due to the replacement of the historical cost as a basis for fair value measurement. Even if fair value is aimed at improving the balance sheet value measurement tools and reflecting a relevant and current business valuation, it is the engine for creating prerequisites for creative accounting, especially with regard to asset valuation.

The techniques and practices used for intangible assets having as effect shaping the outcome, the authors mention:

First, an optimistic attitude regarding the chances of success of a development project will lead to the capitalization of development costs, with implications for the size of the result, the capitalization for the year. In future exercises, expenses recording with amortization will impact the result in the sense of decreasing it. If the enterprise has the interest payment of development costs in the profit and loss (expenditure) it will claim that at least one of the conditions stipulated by IAS 38 para. 43 is not met.

Second, undervaluation of assets acquired by the company leads to increased goodwill. Capitalization and amortization of goodwill over its useful life will influence the outcome in future years (goodwill amortization costs lead to diminished results, with consequences on the course of action and competitiveness of competitive stock takeover bids). Charging goodwill on equity to reduce their lead, results in their diminishing, the result of future exercises not being influenced by goodwill amortization expenses (Hou et al., 2015).

Regardless of the creative accounting method used, the result of its application is aimed at influencing the entities' results and altering the financial statements (Parker, 2012). Creativity when it comes to account balancing means presenting whichever information is desired without violating any international accounting or reporting standards or legal provisions.

Balancing accounts, even if it is not ethical, cannot be considered an accounting fraud because of the limitation of legality. The main reason for the appearance of account balancing is the conflict of interests of different users of the financial information, which have the same expectations as to the qualitative characteristics of the information, but different purposes when it comes to its use.

One of the main qualitative features of accounting information is credibility, which implies the absence of significant errors, lack of bias and fair and reasonable representation of reality, attributes that exclude the use of creative accounting practices. Neutrality is another qualitative characteristic at the opposite of account balancing.

RESEARCH METHODOLOGY

The procedures of financial engineering used have at their base the choices permitted by accounting regulation, the possibilities given by the weaknesses and deficiencies of the accounting norms, and the mechanisms through which accounting can intervene: the determination of accounting interpretation of a legally-financial transaction or the elaboration of a legally-financial mechanisms having the purpose the modification of results of financial situations (Florou & Pope, 2012; Allen & Ramanna, 2013).

Table 1 reviews some creative accounting methods, techniques and practices that have some influence on modelling the result:

As we can see in Table 1 the first effect of creative accounting is hiding fraud and masking financial scandals, as it is very difficult for users of financial statements to analyze the results they are offered in detail - whether they do not have the necessary knowledge or do not have access to the data necessary for the financial statements. According to studies, even the most sophisticated analytics users can ignore or misinterpret certain signals that indicate the practice of creative accounting (Azeita, Austin & Imuentinyan, 2019; Bettner & Kate, 2013; He, Pan & Tian, 2017).

The opportunity to choose accounting methods may be decreased by reducing the number of permitted accounting methods or by specifying the circumstances in which each method must be used. It is interesting to note that the auditors should step up their efforts to identify possible manipulations of the information provided by the financial statements (Cahan & Sun, 2015). In this respect, the audit function should include an assessment of the company's internal control system to prevent creative accounting

Table 1. Creative accounting methods, techniques and practices

Balance sheet item and / or profit and loss account	Mechanism and impact on result modelling
Fixed assets	The practice of 'subjective depreciation' of assets creates a field conducive to creativity in accounting. Based on the exercise of professional judgment, IAS 36 requires that at each balance sheet date, it is determined whether there is any indication that the asset underwriting has been impaired. If the enterprise's management considers the recoverable amount to be less than the net book value, the asset is considered to be impaired for the difference. In this situation, the result will be affected by recording a depreciation expense.
Development costs	An optimistic attitude regarding the chances of success of a development project will result in the capitalization of development expenditures, with consequences on the size of the result, in the capitalization exercise. In future exercises, the recording of depreciation expense will have an impact on the result to diminish it. If the enterprise has an interest in transferring development expenses to the income statement (at expense), it will be invoked that at least one of the conditions set out in IAS 38, paragraph 43 is not met.
Goodwill	Under-evaluation of the assets of the acquired company leads to the increase of the goodwill. Capitalization of goodwill and its depreciation over its useful life have an impact on the result of future exercises (amortization of goodwill leads to a decrease in the result, with consequences on the stock exchange rate and the competitiveness of competitive bidding). Impairment of goodwill on equity results in the decrease, and the result of future exercises is not influenced by amortization of goodwill.
Stocks	The 'stocks' field provides enough opportunities for subjectivism and creative accounting. A discrepancy found voluntarily in determining the stock size in the estate at the end of the exercise may lead to a "smoothing" of the outcome, meaning that the under-valuation or overestimation of the final stock has a bearing not only on the financial statements of the current exercise, but and those that belong to the next exercise. On the other hand, the inclusion of financial expenses in the cost of inventories has the effect of increasing the result in the year in which the expenditure is included. On the opposite side, if the enterprise's management has a pessimistic view of the outcome, it will apply the result method by treating interest as an expense item of the current exercise.
Provisions for risks and expenses	The practice of provisions (increasing and reducing them) is an effective tool for "smoothing" the outcome. The provisioning of provisions in those years in which the enterprise generates profit leads to a reduction in the result, while the resumption of earnings in provisions in the years when the enterprise records a deficit leads to an increase in the result.
Construction contracts	The choice between the two methods of accounting for construction contracts has the following impact on the profit and loss account: on the basis of the completed contract, the result will be recognized when the contract is finalized; based on the finalization percentage method, the result will be spread over time over the entire duration of the contract. Changing from one method to another also has a significant impact on the profit and loss account.

or fraud. In order to ensure broader and more rigorous supervision, auditors should be willing to fight against their clients. This could lead to a radical reflection on the nature of the relationship between auditors and managers. It should not be neglected those concepts such as: integrity, objectivity, confidentiality, competence and, last but not least, credibility must be found in the conduct and documents of the work of any professional.

At the same time, the accounting result represents an important component of the value of a share (Andon, Baxter & Chua, 2007). There have been few cases when very Romanian profitable companies have gone into liquidation. That is why the stock market authority should sensitize investors about the indispensability of education and information, but this is a lengthy process.

Table 2. Accounting methods and manipulating estimates in accounting

Opportunities for creative accounting	Solutions that come to restrain creative accounting	Accounting traditions, where solutions are easy to apply
Choices regarding accounting methods	Reducing the number of allowed accounting methods	Western accounting model
Trends to estimate	Minimize opportunity for estimates	Western accounting model
Entering into an artificial transaction	'Substance over form'	Anglo-Saxon accounting model
Authentic transactions planning	Prescribing revaluations	Anglo-Saxon accounting model

Source: The authors adaptation based on IFRS

SOLUTIONS AND RECOMMENDATIONS

As stated above, creative accounting is seen as a particular feature of the Anglo-Saxon approach to accounting, characterized by flexibility and rationality, to the European continental model, characterized by detailed traditions and prescriptions. The continental accounting model, more prescriptive and inflexible, may be an opportunity to reduce abuses in choosing accounting methods and manipulating estimates in accounting (Table 2).

Financial scandals are based either on the discovery of falsehoods (willing submission of false statements or the dissemination of inaccurate information) or the discovery of the use of techniques to disguise the real situation, known as creative accounting. So, professional accountants long caricatured for their lack of imagination and rigid behavior have created the surprise of inventing creative or imaginative accounting.

FUTURE RESEARCH DIRECTIONS

The presented and analyzed issues are a synthesized part of the vast amount of information that has been developed by the authors to create the framework for understanding manipulating business performances by creative accounting. Therefore, there are new directions of future research such as:

- The choice of accounting methods should be diminished by reducing the number of permitted accounting methods or by specifying the situations in which each method should be used. The imposition of consistent methods is useful because a company who chose a method that gives a positive image in a year, will have to use the same method and during the years when the result will be less favorable.
- The abuse of reasoning can be nipped in two ways: by mapping rules to minimize the use of reasoning or by imposing consistency so that if a company chooses an accounting policy that favors one of the years, they will have to apply it during the coming years even if no longer favors them.
- For artificial transactions „the prevalence of substance over form” concept can be invoked, according to which the economic substance rather than the legal form is the one that determines the accounting substance.
- The time of the transaction is clearly a matter of leadership. However, the purpose of their use can be reduced by requiring the regular review of the elements so that gains or losses of values

change accounts are recognized in accounts for the years in which they appear (and not entirely in the year are transferred).

All these measures against „fraudulent” accounting practices must have the purpose to ensure a qualitative accounting information that faithfully represents reality and to allow decisions to ensure an optimal allocation between participants in value creation.

From the point of view of the accounting practice, the need for an ethical or behavioral code is an obvious matter (Chen, Qu & Sun, 2017). Professional accountants have a delicate position when it comes to the need to provide services that meet high quality standards and serve the public interest, and this is the premise of a need for principles of professional behavior. Thus, the International Federation of Accountants (IFAC) has formulated a set of ethics standards for the accounting profession, which form the Code of Ethics, and highlight the importance of this profession in influencing the organizational culture. In addition to the Code of Ethics, organizations need continuous management involvement as well as professional accountancy organizations working together to implement ethical principles and increase responsibility. Trust is an essential element in business survival, and major economic and financial scandals have demonstrated the fragility of the public or customer confidence.

CONCLUSION

The manipulation of accounting information can be done within the law and accounting rules or outside them (Li et al., 2017). In the latter case there are witnessing an illegal practice: accounting fraud. Although there is a clear difference between creative accounting and deliberate violation of the law (fraud), there is always a clear demarcation between the situation of creative accounting practices and accounting malpractice. Because the law is a two-tailed sword - a control tool, but also an argumentation base for deviating from the rule - the auditors should step up their efforts to identify possible manipulations of the information provided by the financial statements. In this respect, the audit function should include an assessment of the company's internal control system to prevent creative accounting or fraud. In order to ensure broader and more rigorous supervision, auditors should be willing to fight against their clients. This could lead to a radical reflection on the nature of the relationship between auditors and managers. It should not be neglected those concepts such as: integrity, objectivity, confidentiality, competence and, last but not least, credibility must be found in the conduct and documents of the work of any professional.

The fundamental problem of convergence of accounting is linked to the note of credibility given to accounting. The statement is based on the user confidence to the situation where the same public company, for the same period in different countries has different size images in equity and results, as a result of compliance with the rules in these countries.

Also consider that successful convergence IFRS - U.S. GAAP in practical terms depends on the coordination of activity of the IASB and FASB interpretation, because, even if the standards issued by the two bodies will be identical, the financial statements (prepared in accordance with IFRS or U.S. GAAP) will not be comparable (or will be only limited comparable), convergence efforts thus undermined, if the recommendations for the implementation of these standards will also be the same (or comparable).

Europeans are more skeptical of the utility of fair value for other categories of users of accounting information and there are many criticisms about the accounting model. Furthermore, the fair value is unlikely to apply within a Romanian accounting system, all the more so in the context of the loss of confidence in capital markets over the last few years, amplified by the global economic crisis. This is

because fair value is an emanation of the capital market (Ramanna, 2008). Even if the benefits of the fair value system, which are in balance with the disadvantages, are discussed, it cannot be said with certainty that it is superior to the historical cost system. The latter has an incontestable advantage - to be known and therefore mastered.

In conclusion, given the trends of globalization, accounting information users prefer to use an accounting system (concepts, principles, and accounting standards) uniform. As a condition of credibility, the information in financial statements must be complete, in terms of two general restrictions: the cost-benefit and materiality. Omissions can cause information to be false or misunderstood, resulting in a decrease in credibility and relevance.

INTRODUCTION

Globally, Forensic Accounting is coming to be one of the well-fortified expanded domain in the accounting career (Aribaba, 2013). In this chapter, the meaning of Forensic accounting will be examined. This will help create awareness of the significant use of a forensic accountant. Therefore, the objective of this chapter is to discuss the significance of forensic accounting in organizations and industries and the importance of forensic accountant in the detection and investigation of criminal activities such as fraud in an establishment. This chapter will be an eye-opener for the public on how forensic accounting can be used to curb fraud and criminal activities in our organization both locally and globally.

This study intends to evaluate the recognition and avoidance of fraudulent acts or fraud. The following are the objectives to achieve the aim of the study:

- 1) Examine the role of a forensic accountant in fraud recognition and avoidance
- 2) Examine and discuss the techniques that can be utilized in forensic accounting for detecting fraud or criminal activities.
- 3) Examine and discuss the concept of Fraud and forensic accounting
- 4) Discuss the relationship between forensic accounting

Research Questions

1. To what degree is the techniques of forensic accounting for revealing fraud or financial criminal activity reliable and effective.
2. To what degree do the existence of forensic accountant relevant in detecting and avoiding fraud or fraudulent activities.
3. To what degree do the existence of forensic accounting counteract criminal acts such as fraud

BACKGROUND

Meaning of Forensic Accounting

Forensic Accounting (FA) is defined as an ability, skill or knowledge acquired and applied to utilize accounting, auditing. It provides an accounting analysis suitable to be used in legal proceedings. Forensic accounting is frequently used in fraud and embezzlement cases to explain the nature of financial crime

DOI: 10.4018/978-1-7998-3473-1.ch004

in court (Investopedia, 2019). Forensic Accounting necessitates the use of discovering sums of money, asset discovery and recuperation as well as due to meticulousness analyses. FA is also understood as an amalgamation of accounting and investigation practices to ascertain economic corruptions and one of its vital roles is to elucidate the kind of monetary misconduct to the magistrates.

History of Forensic Accounting

The significance of Forensic accounting set out following the year 2008, at that time when doubtful loaning exercises were in place then the massive Bernie Madoff Ponzi system make public extensive carelessness or misdeed and fraud in U. S. financial establishments (Morgan, 2017).

Overview of Fraud

Fraud is considered as an occurrence that is deliberately executed or discharged to obtain a benefit or generate a profit. It is also comparable to deceitfulness in business or the monetary market (My Accounting Degree, 2019). Fraud is considered as a broad legal word indicating a fraudulent deed that deliberately makes use of dishonesty to illegitimately deny another individual of cash, property or legal rights (ThoughtCo, 2019). Fraud depends on the use of deliberate falsification of information to achieve criminal acts (ThoughtCo, 2019).

The following are essential features of fraud (ThoughtCo, 2019)

- i. Falsification of a material fact: A deceitful proclamation encompassing material and pertinent fact need be prepared.
- ii. Realization of falsehood: The individual formulating the deceitful statement must comprehend that it is fallacious.
- iii. Determined to mislead: The deceitful proclamation need have been made deliberately with the focus of misleading and manipulating the target.
- iv. Realistic dependence by the victim: The rate in which the victim depends on the deceitful proclamation must be satisfactory in the sight of the law court
- v. Actual loss or injury suffered: As a consequence of victim dependency on deceitful proclamation, the victim experiences certain definite loss.

The Concept of Fraud

The Electoral and Financial Crime Commission (EFCC), 2004 and Okafor 2004, considered fraud to be a non-violent crime and illicit activity committed with the aim of getting illegal wealth either individually, as a group or an organized manner. Oxford English Dictionary, 2009 also referred to fraud as a wrongful or criminal deception intended to result in financial or personal gain.

Wang, Liao, Tsai & Hung, 2006 and Nwaze 2012 saw fraud as a planned tricky process or device usually undertaken by a person or group of persons with the full intention of cheating another person or organization to gain ill-gotten benefits.

Houck et al 2006 argues that forensic accountant requires unique skills and professional knowledge and training that is beyond academic degree. He also argues that for forensic accountants to be effective he must acquire relevant skills and knowledge. Forensic accounting came into existence due to failure of traditional auditor to detect and prevent fraud and other economic crimes.

According to Anastasia, 2018 forensic accounting is used to determine

- 1) **How:** How the nonconformity had taken place
- 2) **Where:** At what level of the bureaucratic chain had the nonconformity transpired
- 3) **What:** Is the nonconformity deliberate or not
- 4) **Why:** The purpose or aim for the deliberate discrepancy
- 5) **Who:** The individual that is at responsible for the act

Forensic accounting proficiencies facilitate an accountant to collect substantial proofs an occurrence of fraud besides other financial crimes and present it most often in a courtroom. It is, therefore, necessary for a forensic accountant to be well known both accounting and law to establish if financial misconduct had transpired or not. Top Accounting Degree discussed 5 important skills for a Forensic Accountant that will allow a forensic accountant to deliver effectively and efficiently. The skills are discussed below as follows:

- a) **Detail-Oriented Approach:** This involves the procedure of discovering financial indiscretions as well as observing any minimal inconsistencies that could signify a higher pattern of fraud that requires a careful focus and attention. Documentation of forensic accountant investigation should be structured.
- b) **Interviewing Skills:** Forensic accountant congregates facts as well as pursue improve understanding of a condition by cross-examining individuals. A Forensic accountant should be able to identify if an individual is being honest alongside with deciding when they require to drive for additional shred of evidence. A forensic accountant should also possess an attribute of good listening.
- c) **Analytical Skills:** These analytical skills acquired by a forensic accountant can be utilized to create a representation of what type of monetary misconduct may have transpired to make known that indications to others.
- d) **Communication Skills:** This skill is needed to be able to noticeably converse their deduction in both spoken and printed patterns. They must possess the skills of both strong writing and speaking.
- e) **Creative Thinking and Problem-Solving Skills:** They should be versatile and give solutions to difficulties effectually. They should possess the ability to envisage several sequences of events and potentials as well as take account of as to if they are unswerving with the evidence gathered or not

Some examples of Fraud by ThoughtCo, 2019 includes

- a. Mail fraud and wire fraud
- b. Tax fraud
- c. Stock and securities fraud
- d. Medicare and Medicaid Fraud

Some of the commonly committed crimes as stated by legaldictionary, 2019 are as follows

1. **Check Fraud:** This transpires once an individual pay for something with a check intending that there is not sufficient cash in the account to ensure for the cost.
2. **Internet sales:** This involves vending counterfeit stuff, taking payment with no intention of supplying the commodities or substances to customers.

3. **Website misdirection:** This implies imitating trustworthy establishments such as Amazon, eBay, etc.
4. **Charities fraud:** Illegitimate persons seek individuals to make assistances to countless foundations that do not exist.
5. **Work-from-home scams:** The usually called cybercrime such as yahoo yahoo
6. **Pyramid schemes:** It is like a multilevel business that is money is only made when we get a huge number of individuals to join beneath them.
7. **Identity theft:** They deprive preys of their fund, credit rating and private identity by acquiring their private information for their gain.
8. **Credit card fraud:** Individual's card information is obtained through various mediums; the criminal can speedily make a huge volume of purchases far before the consumer realizes what is happening.
9. **Debt elimination:** Many Americas in debt are easily being presented the prospect to clear their bills, the prey then fronts the expense with their credit card information and get nothing as profits.
10. **Insurance fraud:** This means false insurance that is referred to as claiming for automobile damages, medical bills, overheads, and proprietors are considered to be insurance fraud

Once it comes to revealing fraud, three forensic accounting methods can be utilized according to Anastasia 2018. They are

- 1) **Data mining with computers:** Data mining is concerned with considering inconsistencies, tendencies and forms in the datasets connecting to the business and its funds. Data collected during the investigation process is stored and processed with a remote server such as computers (Ogundokun, Afolayan, Adegun & Afolabi, 2019).
- 2) **Review of other documents using various methods:** Information is not continuously in digital form which means forensic accounting has to utilize documents reviewing tactics to spot fraud in an organization.
- 3) **Conducting interviews:** Forensic accounting doesn't only depend on datasets, conversation with personnel and other significant individuals is another fundamental approach to aid recognize data.

Functions of A Forensic Accountant

A forensic accountant is somewhat an accountant and at the same time partially an investigator. He or she is referred to as somebody who attends and manages broad investigates of financial statements and as well as analyses the trails of business dealings and also detects resources for repossession. They work for accounting organizations, risk management consulting companies, law firms, law enforcement agencies, insurance, companies, government agencies, and financial institutions. A forensic accountant has to be proficient and usually obtain qualifications as certified fraud examiner (CFE), certified public accountant (CPA), certified forensic accountant (CFA), chartered accountant (CA), certified management accountant (CMA), certified valuation analyst (CVA), certified fraud examiner (CFE), certified valuation analyst (CVA), certified in financial forensics (CFF), and investigative & forensic accountant (IFA) (Morgan, 2017). Forensic accountants are individuals that investigate, translate and encapsulate complicated monetary and corporate matters. They also accumulate fiscal proofs, establish computer applications to administer the information gathered and relate their discoveries in the format of records and performances (Investopedia, 2019).

The function of forensic accounting cannot be under projected in discovering fraud in the Nigerian's public subdivision (Amake & Ikhatua, 2016). Owojori & Asaolu 2009 specified that the function of a forensic accountant is distinctive from that of conventional auditor and it is appropriate to an establishment. They also identified that a forensic accountant makes use of secretarial, inspecting and scrutinizing skills while performing exploration and they are educated to look outside the range of dispute in numbers of ways.

Crumbley & Apostolou 2005, asserted that an expert in forensic accounting has a specific willing emphasis on exposure and avoidance of fraud. Forensic accounting frequently encompasses the precision of strives to infiltrate suppression strategies (Krell, 2002). Forensic accountant focuses on fraud discovery, documentation of precise proof necessitated for efficacious illegitimate examination, provide primary suggestion as an evaluation of the persuasion and indication accessible at the beginning of the procedures, evaluate and ascertain fundamental credentials which ought to be obtainable as proof, formulate a comprehensive steadiness on considerable proof which is fathomable, analyze professional accounting report and lawful guidance on financial and accounting concerns.

Forensic Accounting for Criminal Investigation

Forensic accounting is used to discover whether a crime occurred and assess the likelihood of criminal intent. Such crimes include employee theft, securities fraud, falsification of financial statement information, identity theft or insurance fraud.

Forensic Accounting Services

In 1995, KPMG discussed forensic accountant is often involved in the following activities;

1. Fraud Awareness Workshop
2. Investigation
3. Asset Tracing
4. Litigation Support
5. Business/Employee Fraud Investigations
6. Mediation and Arbitration

Methods to a Forensic Accounting Assignment

Each forensic accounting assignment is unique and generally much forensic accounting assignment would include the following steps below (Aribaba, 2013)

- i. Meeting with the client: Interacting with clients to apprehend the significance of the shreds of evidence and concerns within reach is extremely advantageous.
- ii. Performing a conflict check: Once the appropriate persons are recognized, a dispute validation would be accomplished.
- iii. Performing an initial investigation: Executing a preparatory analysis which is preceding to the progress of a comprehensive design of activities which permits following preparation to be centered on at that time.

- iv. Obtain the Relevant Evidence: These shreds of evidence could encompass discovering documents, financial restoration, assets, an individual, firm or enterprises and so on and this relies on the kind of the incident being investigated
- v. Develop an Action Plan: The information gotten by consulting with clients and accomplishing the primary inspections are brought and put into consideration. The goals of the investigation to be accomplished and the approach to make use to achieve the tactics are also being considered.
- vi. Perform the Analysis: The real investigation executed will be determinant upon the kind of the obligation.

Literature Reviews

Bhasin 2007 defined forensic accountants as trained personnel who look beyond the figures but deals with the business certainties of circumstances. In his article, he stated that forensic accounting includes inspecting, evaluation of financial facts, communication of these discoveries in form of details, presents and gather documents as well as also facilitates in legal happenings which comprise of attesting in court as a professional witness and organizing graphical aids to sustenance trial shreds of evidence. An investigation is referred to as the inspection of documents and accounts of an organization for a certain motive.

Zysma, 2004 examined forensic accounting as integration of bookkeeping, inspecting and analytical skills.

Olafinsola, 2007 considered forensic accounting as the presentation of illegitimate approaches besides the incorporation of accounting fact-finding activities and law practices associated with the detection and investigation of financial misdeeds and correlated monetary criminal acts.

Manning 2002 defined that forensic accounting is the utilization of financial accounting and analytical skills to a code of behavior satisfactory by the court to attend to concerns in a debate in the framework of civil and criminal legal proceeding. Forensic accounting was ascribed by Joshi (2003) to Kautilya who is the first economist to openly recognize forensic accounting and is an area of study that is fast advancing. It has significantly become a field of attention to auditors and accountants.

Fraud

Fraud is referred to as the unlawful act of being duplicitous to an individual(s) in order to obtain money or possessions illegitimately (Oxford Advanced Learner's Dictionary, 2010). Fraud was also considered as an act of making oneself richer by deliberately apprehending the worth or wealth of an asset in an undisclosed manner (Arzova, 2003). Okafor 2004 described fraud as a forensic term that encircles diverse (Jones, 2011) means which human's imagination can devise that can also be resorted to as one person is receiving advantage over another in deceptive representation. Fraud can also be described as treading outside the authoritarian structure intentionally to provide a deceitful representation of the accounts (Jones, 2011).

Adeniji 2004 along with others summaries the varieties of fraud on the foundation of the approaches of perpetration made by criminals. The fraud categories are as follows but not limited to the following

- a. Defalcation
- b. Suppression
- c. Outstripped
- d. Theft and Embezzlement

- e. Tampering with reserves
- f. Insider abuses and forgeries
- g. Fraudulent substitutions
- h. Unauthorized lending
- i. Lending to ghost borrowers
- j. Kite flying and cross-firing
- k. Fake payment
- l. Fraudulent use of a firm's documents
- m. Fictitious contracts

Fraud is a theme that matters a lot and has received a lot of attention both globally and locally (Oyejide 2008).

Bozkurt 2003 stated in his study that two kinds of fraud are perpetrated in business and they are personal use of business resources and secondly is drawing up of financial statement of business falsely. Studies have revealed that the total loss in public subdivision as an outcome of workers' deceitful deeds is extremely larger than that experienced as a consequence of populace carelessness (Amake & Ikhatua, 2016). Around 50% of workers are unwavering to perpetrate fraud whereas 80% of the workers could be liable to perpetrate fraud under an appropriate circumstance (Owolabi, 2007). It was also observed that most of the fraud perpetrated on the public subdivision were mostly perpetrated by married men than the unmarried with an outstanding level of education and extremely high IQ level and their ages are 28 years and above. They are in an appropriate working atmosphere, delegated with being in charge of accountability of taking care of fraud or their partners and they also established in money-spinning posts in an establishment. Forensic accounting had become a complex area of concern for the accounting profession (Okeye & Gbegi, 2003).

Emeh & Obi, 2013 conducted an empirical analysis of forensic accounting and financial fraud in Nigeria. They inspected the relationships of the presence of forensic accountant, the number of accountants with forensic accounting skills, the extent of forensic accounting practices, the extent of employee theft, the extent of financial fraud and extent of top management fraud. Their study gave a conclusion that there was any evidence of significant negative correlations between the presence of forensic accountants, the number of accountants with forensic accounting skills, and extent of forensic accounting practices with the extent of financial fraud.

Dada, Owolabi & Okwu, 2013 tried to take care of the importance of forensic accounting in a successful decrease in fraudulent performs in Nigeria. Their study resulted in disclosing that fraud decrement is important and connect or correlate with fraud investigation and exposure utilizing forensic accounting.

The Need for Forensic Accounting

The requirement of forensic accounting stimulated as a turn-out of no-success of audit method in businesses to discover fraud and other duplicitous happenings. Experts in this study area of accounting have perceived that concentrated economic difficulty has steered several people into fraudulent happenings in a great amount of business or enterprise. Forensic accounting program was devised to assist accountant advance with a fact-finding eye as regarding both the internal and external fraud and makes available crucial evidence to handle the issues when revealed (Amake & Ikhatua, 2016). Forensic accounting is a novel and speedy emerging area in the accounting field of study which is more or less like a conduit or channel linking accounting schemes to legal schemes (Mayungbe, 2012).

Skill of Forensic Accounting

Forensic accountant needs skillful and qualified expertise to be effectual in the enactment of obligations (Amake & Ikhatua, 2016). (Aderibigbe, 2000) recommended that a forensic accountant needs an extraordinary level of proficiency, uprightness, and trustworthiness to execute his job and be meticulously expert to demonstrate his proficiency by performing well in all appropriate investigation to become a representative of renowned accounting association. Forensic accounting field of study comprises of distinctive abilities that normally necessitates additional coaching outside an academic degree in accounting, Certified Public Account, Certified Fraud Examiners or any other certification. Forensic accountant ought to acquire understanding, proficiencies, and capabilities in the following areas listed below (Houck, Kranache, Moris & Robertson (2006):

1. Accounting and auditing skills
2. Criminology, lawful, authoritarian, certified setting and practical disputes
3. Fraud discovery, deterrence, investigation, and remediation in the following areas such as facilitate embezzlement, corruption and false representation of financial statement, fraud and forensic accounting established instruments and procedures for identifying and inspecting, automated incident supervision instruments and lastly other exclusive to computerized atmospheres
4. Loss deterrence
5. Forensic and lawsuit consultative assistances, incorporating research and investigation authentication of fatalities and impairments

FUTURE RESEARCH DIRECTIONS

This study can further be researched by implementing the techniques of forensic accounting reviewed in this study in a real life such as accounting organization worldwide. Forensic accounting can be adopted by many organization so as to make the business to continue to grow by making more profits. The following future research directions are listed below:

- a) More criminal and unlawful acts can be researched and reviewed on
- b) Implementing this study in real life both in accounting sector and legal court
- c) Adopting and using the techniques of forensic accounting in detecting fraud in organizations, banking sectors and so on and the criminal offences detected can be useful in legal court
- d) Government adopting the use of forensic accounting in the country economic

CONCLUSION

Fraud can occur in any company which can either be big, small, medium businesses. Revealing fraud can be challenging but forensic accounting delivers fairly a good number of clarifications to ascertaining whether a duplicitous activity has taken place or not. It, therefore, concluded that the study examined how forensic accounting can be used to detect fraudulent or criminal acts in a financial statement or organization. Also, the technique of forensic accounting that can be used in the detection of fraudulent acts committed was discussed.

KEY TERMS AND DEFINITIONS

Court: This is referred to as a gathering to handle legal activities. It is also a territory in which a judges, lawyers, and people convene.

Criminal: This is an individual who responsible for a misconduct or an unlawful act and had been legitimately declared guilty of the offence.

Criminal Acts: This is referred to an illegal or unlawful attitude of an offender or criminal.

Criminal Investigation: This is referred to as the inspection or consideration of an offence or misconduct that is illegal or unlawful perpetrated by an individual.

Data Mining: Data mining refers to as data treatment by means of advanced data inspection competence and statistical procedures to ascertain patterns and associations in an already existing large database to uncover novel significance in data.

Financial Statement: This is a record presenting transaction's credits and debits.

Forensic: This is used in investigation and consideration of proofs or indication in a law court.

Forensic Accountant: This is an individual that uses secretarial abilities in scrutinising fraud or any form of criminal acts for use in legal court.

Forensic Accounting: This is defined as the practice involving secretarial abilities to scrutinise fraud or any form of criminal acts for use in legal court.

Fraud: The refers to something or an individual that consciously cheat, pretend, or trick with the aim of making profit as a benefit and this act can cause a harm to the victim.

The Necessity of Acting in the Public Interest: Corruption and Fraud in the Public Sector

INTRODUCTION: THE CONCEPT OF PUBLIC INTEREST

The concept of public interest (Canning and O'Dwyer, 2001: 728), which is an issue where universal acceptance cannot be achieved as to what it is and how it can be measured, has an interdisciplinary importance and meaning today. Moreover, according to Sturm (1978 cited in Dellaportas and Davenport, 2007: 1084), it is at the centre of interpretations in political and social life.

Although the roots of the concept of public interest in the modern sense were first introduced by the French Revolution of 1789 (Saraç, 2002: 1), it can be said that the concept originated from the “common good” applied in England in the 17th century (Dellaportas and Davenport, 2007: 1084). Traditionally, common good is clearly a political idea and consists of some specific goals designed to promote the general well-being of all people, such as peace, order, prosperity and justice. Special goals, which were surrounded by common good until the mid-17th century, led to the collapse of medieval feudalism in England and the gradual disappearance of common good with the rise of national monarchies, and to clarify the distinction between common good and public good (Douglass, 1980, p. 107). In this context, the concept of public interest, which took its place as a separate concept in the literature, developed primarily with its managers or representatives interested in the material welfare of individuals rather than the welfare of the state. Then led to the attachment of individual welfare to the property rights and private interests of British property owners (Dellaportas and Davenport, 2007).

Although the public interest has developed its own identity, it remains a concept that cannot determine the content of the public or public interest. According to Gunn, the basis of this is that the term “interest has no definite meaning (Dellaportas and Davenport, 2007). The effects of uncertainty in the concept of interest can be found in P. Herring's study. According to the author, in fact the laws passing through the parliament are full of uncertainties and sometimes are ‘parliamentary’ activities that sometimes occur ‘so that they do not grow’, and the task of bureaucrats is to produce public policies which are operative from these unqualified obligations, and even this process can often be described as the public good itself (Shafritz et al. ., 2015). In addition to Herring expression, Flathman (cited in Dik, 2005: 3) points the process as a tool that the government considers while producing policies and provides legitimacy for the administration to carry out its activities easily.

Today, the concept of public interest, which forms the basis of the state and administration in the modern sense, tries to get rid of the uncertainty mentioned above and the law itself and everything that

DOI: 10.4018/978-1-7998-3473-1.ch005

is legal, is defined as public interest (Saraç, 2002). In this study, first, explanations of corruption and fraud are brought to the necessity of the concept of public interest for both the private and public sectors. Then, in the context of the necessity of acting in the public interest for public institutions, explanations and evaluations regarding the phenomenon of corruption and fraud are given.

The Case of Corruption: The Necessity of Acting in Favour of Public Interest

In the literature, fraud and ignoring the principle of public interest lie at the root of corruption incidents. Corruption is a phenomenon dating back to ancient times (Tanzi, 1998: 559). With the definition adopted by the World Bank, corruption is expressed as the abuse of public power and resources of private interests (Tanzi, 1998: 564; Bardhan, 1997: 1321; Huntington, 2002: 254). The public administration glossary defines the phenomenon of corruption as fraudulent, improper, irregular work and behavior that occurs in violation of the rules, is not done properly. Again, in the literature, the concept of corruption in the legal and sociological sense is expressed as the fraudulent use of public duties, powers and resources contrary to the legal and social norms and standards that form the basis of social order (Uğur, 2012: 302-304). By linking the concept of corruption to fraudulent acts (Özbaran, 2003: 18), the Council of Europe Convention on Anti-Corruption Private Law defines bribery that directly or indirectly leads to deviations in the lawful performance of the duties or conduct of a person who obtains an illegal interest (cited in Yardimcioglu et al. 2014: 172).

In the accounting literature, the concept is explained on the basis of professional ethics and this requires a realistic presentation of the information provided by private or public enterprises. Although the concept of corruption refers to the use of personnel in public institutions in order to achieve specific results by violating the accepted norms, corruption is also observed in all societies but in every society in different ways than others. This situation arises when there is no effectiveness of political institution-alization. Especially in a society, as the differences between political development and modernization increase, it is possible to see various forms of corruption (Huntington, 2002: 254). However, although the explanations do not directly express corruption and similar activities in private sector enterprises, it is also known that regulations are made at the public level for events taking place in terms of private sector enterprises (Tanzi, 1998: 564).

In this context, it is possible to say that the necessity to act in the public interest constitutes the common point in the definition and the explanations about corruption. According to Shaub and Braun (2014: 5), the public interest approach is one of the most controversial parts of the accounting and auditing profession and the code of ethics. This controversial section may lead to the uncertainty of the concept in other areas of the literature. The International Federation of Accountants (IFAC - 2012) defines the public interest as follows:

“The net benefits derived for, and procedural rigor employed on behalf of, all society in relation to any action, decision or policy.”

As can be seen from this definition, the concept of public interest embodies a professional structure that produces good results for the general public in accounting. In particular, the four sources used by IFAC (2012) in developing the concept of public interest are important to explain the scope of this definition. The first source in the development of the concept is the meaning of the concept of public interest in the literature of politics, economy and psychology. The second source is the study of the studies emphasizing the relationship between public interest and accounting in the professional and academic literature,

and transforming the concept to include regulation, standard setting, market deficiencies, ethics, conflict of interest, corporate governance and accounting crises and scandals. The third source is the views of IFAC and other stakeholders regarding the concept, and the fourth is the examination of the concept in terms of IFAC's own regulations and objectives. The sources used in the definition of the concept are adopted in explaining the terms within the definition.

While the term of 'public' covers all internal and external users of the organization and the entire society; the term 'interest' includes the financial and non-financial information used in decision-making, all kinds of benefits that can increase the comparative presentation and efficiency. Again, IFAC sets two basic criteria for assessing public interest. The first is the evaluation of benefits and costs, the second is the evaluation of the process. The evaluation of the process is based on the criteria of transparency, accountability, independence, competence and professional care. IFAC's paper also describes the fact that the member of the profession stated in the announcement observes and applies the ethical rules while acting in the public interest (IESBA, Code of Ethics, 2018: Section 100.1). This leads us to another point that is as controversial as the understanding of the public interest, that is to serve the public interest. Proper action or service of the public interest is defined as an important means of combating corruption on the one hand, and on the other hand it requires consideration of the phenomenon of fraud, which represents an even higher concept for the public good.

The Case of Fraud: The Necessity to Act in Favor of Public Interest

Fraud refers to a crime on the basis of the phenomenon and means that one person makes a false statement to the other in order to gain a certain benefit (Singleton et al., 2006: 1) or that an intentional illegal action is taken in order to get more interest. In other words, fraud is defined as the intentional deception or misrepresentation of nonconformities and unlawful acts that a person knows is wrong or does not believe in the correctness (Emir, 2008: 112). Fraud is of great importance in terms of accounting system and financial reporting both in public and private sector organizations. This is because the existence of fraud reduces the possibility of a full assessment of the accounting system and leads to a direct misjudgement and even an ineffective use of resources to violate the concept of public interest. Whether the fraudulent application is large or small in amount does not change the damages or negative effects of the fraudulent case. Quantitative value does not reduce the negative effects of fraudulent transaction (Singleton et al., 2006: 3). What is important here is whether the process subject to fraud is done consciously. Therefore, the distinction of fraud from errors and inaccuracies must be made well and clearly for all organizations.

Fraudulent financial reporting, which is considered to be a direct relationship with fraud, refers to the preparation and presentation of financial statements in order to deceive all information users, particularly those of the society, the public, investors and fund institutions, by deliberately altering the information in the financial statements or eliminating actual evidence. At this point, fraudulent financial reporting occurs in cases where the top management of all organizations cannot bear the responsibility of providing accurate and reliable information during the preparation of financial statements, or prevents the financial reporting process from being honest and high quality, or the fraud cannot be detected or prevented during the audit process (Rezaee, 2002: 1-2).

In accordance with the explanations, fraudulent financial reporting can be said to be a criminal offense caused by the deliberate distortion of financial statements. Fraudulent financial reporting is the deliberate misrepresentation of users of financial statements by omitting or misrepresenting the amounts or disclosures required in the financial statements. Merchant (1987) also defines fraudulent financial

reporting as presenting by changing or altering financial documents, deleting records and eliminating information (Powell et al., 2005: 7).

In order for the fraudulent financial reporting process to be realized, the necessary elements must be defined. The theory developed by Donald R. Cressey in the late 1940s, the so-called “fraud triangle” reveals these elements in a well structured way. According to this theory; In order for fraudulent financial reporting to be potentially available, at least one of the three situations must exist. This approach, which constitutes the underlying theory of fraud risk factors, was dealt with according to Cressey’s theory in SAS No: 99, and the validity of all three situations in a fraud triangle was indicated in a trick. However, according to the approach in SAS No: 99, it is asserted that these three situations generally exist in fraud environments, but the presence of a single element in the fraud triangle is deemed sufficient for the fraud potential to occur (AICPA, SAS No: 99, Paragraph 7; Küçük, 2008 Skousen, 2004: 7; Wolfe and Hermanson, 2004: 38).

Fraud risk factors are classified according to the elements in the fraud triangle (Skousen, 2004: 6–12; 82). According to this approach (see Figure 1), the situations that exist in the environment where the fraud is committed are as follows (AICPA, SAS No: 99, paragraph 7, Küçük, 2008: 50-51):

- *Pressure (Incentives and Coercion): There are certain incentives and / or coercion elements such as profitability targeting, performance-based remuneration that motivate management or other employees to commit fraudulent behaviour.*
- *Opportunities: Some conditions, such as inadequate controls, inefficiency, or management’s ability to frustrate controls, provide some form of opportunity for fraud.*
- *Attitudes and Legitimation (Rationalization): Those who commit fraud can legitimize their fraudulent behaviour in accordance with their personal understanding of morality and try to excuse it. Some people’s moral understanding may allow them to behave intentionally and unintentionally. On the other hand, in situations where there is sufficient pressure, even those who do not expect such behaviour may be involved in fraudulent behaviour. The greater the incentive and pressure, the greater the chance that a person can legitimize the act of fraud.*

Figure 1. Fraud Triangle

Figure 2. The Fraud Diamond

The fraud triangle and the fraudulent financial reporting environment have become more understandable for both the main actors such as businesses and auditors. However, in the following period, various contributions were made to this theory and a new theory was proposed under the name of cheating triangle. This theory is illustrated in Figure 2:

Wolfe and Hermanson (2004: 38-40) re-evaluated the elements related to fraud in their research. They found that besides the elements in the fraud triangle, the ability, capacity and capability of the individual played a major role in the detection of fraud. From this point, they have put forward the theory of *the fraud diamond*. Fraud diamond theory and elements of fraud; pressure, opportunities, rationalization and capability. Thus, it is seen that the ability or capacity of the individual is of great importance in detecting and preventing fraud.

In line with the explanations, it can be said that the incidence of fraud in both public and private sector organizations occurs with the presence of at least one of the dynamics mentioned above. In this context, the evaluation of the phenomenon of fraud for all institutions once again reveals the necessity of the concept of public interest. While the concept of public interest on the basis of the phenomenon of fraud includes all kinds of deliberate transactions that prevent the effective use or distribution of public resources for public institutions, the concept of public interest in private sector enterprises provides information misleading decision-making processes of all external information users and internal information users. it becomes a situation that needs to be evaluated in a wide range from unrealistic reporting. Thus, the oversight of the public interest for all stakeholders can be facilitated.

CONCLUSION AND DISCUSSION: CORRUPTION AND FRAUD IN THE PUBLIC SECTOR

The concepts of corruption and fraud, discussed in detail above, are difficult to define in the public sector but easy to recognize. Proof of these events is often not possible. It is generally seen that certain behaviors indicate corruption and fraud. However, the emergence of corruptions and their transfer to the judiciary generally necessitates the existence of a conflict of interest or the spread of unethical behaviors in the public sector. As can be seen here, corruption and fraud in the public sector; It is a phenomenon based on personal interest and dispersed by conflict of interest. According to many disciplines; corruption defined as attempting to maximize personal benefit; it is directly related to the lack of control of personal interests in the production process. (Turan, 2014). On the other hand, corruption can be described as a

kind of “public bad” that emits negative externality (Çelen, 2007). In a World Bank report, this conflict of interest, characterized by its negative externalities, described it as “abuse of public power for private interests (WB, 2014). The phenomenon of corruption involves the existence of the two sides and the exchange relationship between these two sides. In the face of an interest provided to the other party, those who hold the public power gain an interest. This interest can be on the one hand material values such as money or goods; and on the other hand, they may also be intangible values such as authority, position, prestige, and political interest.

As mentioned above, in cases of corruption and fraud in the public sector, a trade-off (or exchange) relationship between the two parties should be realized. In this exchange process one of the parties is authorized, which in most cases refers to the representative of the state authority, (usually the public official or the civil-servant). In this context, when we look at the definitions of non-compliance with the public interest or corruption and fraud in the literature, we see three common elements. These are (1) the existence of an authorized person or a public official, (2) the use of authority and behave against the rules and (3) the elements of gaining benefits. Some authors add the element of ‘secrecy or confidentiality’ to these elements (Özsemerci, 2002). However, the existence of these elements is constant in all cases of corruption. The first of these elements is authority. The concept of authority, without making any distinction between public and private sector, is expressed as the power of person or persons to use common authority or joint decision-making power (TEPAV, 2006). As it has already been mentioned the purpose of corruption is to gain interest and thus one of the parties to corruption will use these powers to gain benefits. In other words, the person or persons who are the side of corruption has the authority to serve their interests (Berkman, 1988: 10). Abuse of authority and acting out of authority is a combination of monopolistic power and discretion.

The second element of corruption and fraud in the public sector is the being against the rules. In a “rule of law” situation social life and the organization of the state are regulated by various rules. In the case of corruption, the public official’s misconduct these rules for material gain or special purposes arises. A part of these rules are the laws that are written and applied by the state. Corruption, regardless of which rules, whether written or unwritten, involves not following the order, deviating from the rules (Yavuziğit, 1996). In a such case irregularity or illegality brings corruption and corruption brings irregularity, which can be defined as a vicious circle. In other words, in the case of illegality corruption is not an exception. This does not undermine the irregularity principle of corruption. Because corruption is contrary to moral rules in all circumstances, even if it is done within the legal framework. For example; the behavior of a public official who ignores the shortcomings of an enterprise within the framework of the legal procedure, although not contrary to the law, is contrary to the code of ethics. Or, the application of the public officer who gives work- permission to an institution by falsifying documents is contrary to the written rules and illegal. This is subject to criminal sanction under the law. As can be seen, not only the dimension of non-compliance with the written rules (laws), but also the dimension of non-compliance with the unwritten rules (moral rules) is important in the non-compliance with the rules.

The abuse of authority in the process of corruption leads to a violation of the rules, ultimately gaining interest in these two elements, the third. An interest item with a material or moral value that will serve the interests of the public official and the decisions and procedures of the public official are required to be influenced. When corruption occurs, both parties gain in line with their own interests, and in some cases, the person making the corruption earns interest alone (Berkman, 1988). Whatever the kind, the aim is to gain interest. The interest can be material or spiritual.

In line with the explanations regarding the elements of corruption that has been illustrated above, the most reliable factor in determining the phenomenon of corruption is the “illegal use of authority”.

Since rules exist in social life and in the state organization, it should be considered as corruption that the state uses the authority of the public official in order to gain any benefit, which causes harm to the society or individuals. Accordingly, when the corruption cases investigated in Turkey, not in the form of applications to be against the law in cases of corruption; rather, mutual exchange of interests is observed through legal deviations. In other words, in cases of corruption, practices are often carried out in accordance with the law, but public authority is used in the hands of public officials/civil servants as a means to consciously benefit. This nature of corruption incidents makes it more difficult and complex to detect corruption and to find preventive remedies than unlawful actions and behavior. On the other hand, the efforts of the parties to increase their personal benefits are sometimes effective enough to make the appropriate legal arrangements, and sometimes the circulars and communiqués issued in areas where there are no legal regulations are deviated from their aims and they are tried to be ignored of the acts of corruption (Aktan 2001).

The literature draws attention to the existence of these three elements in almost all corruption and fraud procedures in the public sector. However, different reasons and sources of corruption can be put forward in the emergence of corruption in the public sector. For example, in addition to corruption caused by authority and persons in the public sector, corruption caused by the system also plays an important role. Corruption arising from the system can be explained under two aspects: direct and indirect. Direct factors are those that arise from the existence of the state. In this regard while public expenditures, investment decisions, taxation, procurement of goods and services and presentations directly affect the system; bureaucratic structure, wage levels, attitudes of managers and leaders, control and transparency can be shown as indirect factors (Kutlar, 2015).

In a general perspective, it is possible to classify the different causes of corruption under administrative, political, historical and social-economic sections (Ruslan, 2016). Historical and socio-economic reasons are directly related to the habits of a society both in determining how the concept of public interest will be shaped and in determining which kinds of habits are fraud and corruption. Administrative corruptions include matters related to the actions and procedures of the administration which cannot be defined as a tradition or habit. This kind of corruption occurs in the implementation of state policies and the execution of public services. Therefore, there is always a public official or a public body in administrative corruptions (Özsemerci, 2002: 15).

The main factors in the emergence of administrative corruption are the roles of states and their interventions in social and economic life. Although the functions of current states are regulated within the framework of certain rules, they are obliged to perform certain tasks and services. Activities in areas where the state is responsible are highly susceptible to corruption. For instance, government licenses, documents, permits and tenders for the provision of services are some of the most “attractive areas” for corruption. Another factor that causes administrative corruption is the fact that the authority is left to the civil servants in the use of estate and asset property that may have monetary value (TEPAV, 2006). Another important reason for the occurrence of administrative corruption is bureaucracy. The biggest factors in the formation of bureaucracy are people and the social environment/sphere. These factors play a role in shaping the bureaucratic structure while forming the administrative structure. The quality of the bureaucratic structure, the way it works, has its own characteristics in every country. The quality level of bureaucracy alleviates the effects of political instability, maintains the continuity of government, while complex bureaucracy slows down state levels and increase the possibility of fraud and corruption (Ruslan, 2016).

Another negative factor that triggers administrative corruption in parallel with the bureaucracy is centralization in which central governments have a strong control mechanism on the local governments.

Thus, in these structures, the central government has authority and this brings the monopoly of the center. Therefore in the strongly centralized and hierarchical countries like Turkey, the negativity of highly centralized government may cause disruption and distortion. It is inevitable that there are distortions in such administrative structures and in politics, which are the means of using the administrative power. Under the influence of bureaucracy and centralism, the lack of flexibility, complex and rigid structure of public administration allows corruption in the state levels (TEPAV, 2006).

The negativity in the political field does not only lead to deterioration of the citizen relations with the state, but also minimizes the trust in the state. Deficiencies in public services push those who want to access these services in unlawful ways, and there are cases of corruption where non-legal situations (such as favoritism, nepotism, cronyism, political favoritism, patronage) can be seen. In this case, the state and the citizen, which should form a whole, break with each other and the awareness of “public interest” is completely damaged. Consequently, the social, economic and democratic causes of corruption should not be ignored. Corruption tendencies are higher in less developed and developing countries where the culture of democracy is not fully established (Gray and Kaufman, 1998). Another problem of underdeveloped countries, unplanned population growth, disrupts the distribution of resources and increases the demand for the service sector. The unfair distribution of resources and the quality of monetary policy can also lead to increased corruption in the sharing of public services (Goel and Nelson, 2005). Inequalities and unrest arising from public policies begin to affect society negatively. The people who have lost ties with the state look for solutions in interest groups and illegal ways, which leads to the disappearance of public interest awareness and individual interests in society (Gray and Kaufman, 1998).

In short, the concept and awareness of public interest is an important fact that should be taken into consideration by almost every sector producing and receiving public services in society. The most important factor in the development of this phenomenon firstly in individuals and then in public institutions can be expressed by social, political and economic values. In Turkey, especially when viewed in the bureaucratic structure seen in almost every period in the public sector politicization, nepotism and cronyism processes are prepare for corruption and fraud transactions in public areas. On the one hand, patronage in the bureaucratic processes, authoritarian and over-centralized state structures, and the lack of sufficient public interest awareness in management levels, unemployment and low quality living conditions caused by rapid population growth and distorted urbanization created an environment suitable for the disappearance of public interest awareness and corruption. On the other hand, unqualified public policies and the sharing process of state-generated rent were another source of corruption and fraudulent transactions in the public sector (Özsemerci, 2002).

INTRODUCTION

In stochastic frontier model analysis, it is acknowledged that the estimation of production functions must respect the fact that actual production cannot exceed maximum possible production given input quantities. Consequently, one of the main questions is to investigate the relationship between inefficiency and a number of factors which are likely to be determinants and measure the extent to which they contribute to the presence of inefficiency. Overall, these determining factors characterize the process of technological change. Stochastic frontier models assume that producers operate under the same production technology and that the inefficiency distribution across individuals and time are homogeneous. Estimation of technical efficiency has been the subject of research in many empirical studies on industrial productivity, contributing to the theoretical development and empirical application of SFA at both the firm and industry levels, with the purpose of screening out the external effects and statistical noise from the producer's performance and achieving a more accurate efficiency measure (Wang, 2000). Following these fundamental approaches, there has been a rapid increase in the volume of research on analysis of efficiency in production, both in theoretical and empirical research. Most of the literature focused mainly on stochastic frontier model with distributional assumptions by which efficiency effects can be separated from stochastic element in the model and for this reason a distributional assumption has to be made. Unobservable individual effects also play an important role in the estimation of panel stochastic frontier models. In contrast to the conventional panel data literature, however, studies using stochastic frontier models often interpret individual effects as inefficiency (Schmidt and Sickles, 1984), such as technical inefficiency in a stochastic production frontier model.

This chapter focuses on reviewing the stochastic frontier analysis literature regarding estimating inefficiency in financial markets level, as well as explaining producer heterogeneity along with the relationships with productive efficiency level. The chapter begins with a general overview of the main research papers on estimating productive efficiency in financial markets, both in aggregate and disaggregate level, providing the main hypotheses and results of each case. Then, the chapter continues with explaining producer heterogeneity, as well as the main determining factors towards efficiency differentiations.

A question of interest is whether inefficiency occurs randomly across producers, or whether some producers have predictably higher levels of inefficiency than others. If the occurrence of inefficiency is not totally random, then it should be possible to identify factors that contribute to the existence of inefficiency (Reifschneider and Stevenson, 1991). The important task is to relate inefficiency to a number of factors that are likely to be determinants and measure the extent to which they contribute to the presence of inefficiency. Following these fundamental approaches, there has been a rapid increase in the volume

DOI: 10.4018/978-1-7998-3473-1.ch006

of research on analysis of efficiency in production, both in theoretical and empirical research (Cowan and Salotti, 2015 and Iftekhar and Soula, 2017).

This chapter investigates technical efficiency estimation in financial markets, using both parametric and non-parametric techniques: parametric Stochastic Frontier Analysis (SFA) approach or non-parametric Data Envelopment Analysis (DEA). Contrary to the Stochastic Frontier Analysis approach (SFA), which requires a functional form to estimate the frontier production function and is based on the idea that the data is contaminated with measurement errors and noise (Bauer, 1990), Data Envelopment Analysis (DEA) approach uses linear programming techniques and cannot discriminate between inefficiency and noise. Thus, it tends to produce overestimated inefficiency measures, a fact which is the most important disadvantage of DEA in comparison to SFA (Bauer, 1990). This chapter proposes a slack-based DEA which allows a full evaluation of inefficiency in an industry's performance. The model estimated in this chapter is a DEA variant called slack-based measure, which is able to deal directly with the input excesses and the output shortfalls of the industry under evaluation (Tone, 2001). Estimated slacks are invariant to the units of measurement and are monotone decreasing with respect to each input and output slack. By using slack-based efficiency measure, we obtain different frontier levels and more appropriate performance benchmarks for inefficient industries. The production assumptions in DEA are that all actual observed inputs and outputs of any industries are feasible for all industries, as are linear combinations of observed inputs and outputs.

More specifically, this chapter focuses on reviewing the stochastic frontier analysis literature regarding estimating inefficiency at industrial level, as well as explaining producer heterogeneity along with the relationships with productive efficiency level. The chapter begins with a general overview of the main research papers on estimating productive efficiency in different industries, providing the main hypotheses and results of each case. Then, the chapter continues with explaining producer heterogeneity, as well as the main deterring factors.

This approach suggests the great importance of the interaction between the different determining factors and estimate any implication for efficiency. Over all, the major contribution of this approach is that it provides a better understanding of the contribution of technical efficiency taking into account major interrelationships and complementarities. The purpose is to study financial industries experience in an effort to determine the potential efficiency determining factors and to investigate various aspects of the relationship between efficiency and determining factors in an attempt to reach a better understanding of the contribution of alternative factors to efficiency growth.

This is of value for practitioners, policy makers and the academic community:

1. For industries, in order to make recommendations to firms on identifying, developing and deploying their resources that may influence their technical efficiency, competitiveness and consequently their performance.
2. For policy makers, the value stems for a better identification and understanding of the key resources. This will allow government entities to formulate and implement programs, which will leverage areas of industries, which require further development.
3. Last but not least, the value for the academic community mainly lies on an increased knowledge about the impacts of different determining factors on efficiency estimation.

BACKGROUND

1

One of the most important hypotheses in modern economic theory is based on the assumption of optimizing behavior, both from a technical and economic perspective.

However, not all behaviors succeed in solving optimization problems under all circumstances. In real economic life, it is unlikely that all (or possibly any) behaviors operate at the full efficiency frontier, with failure to attain the efficiency frontier implying the existence of technical inefficiency.

More specifically, a measure of evaluating the performance at producer level is technical efficiency through production frontier, a concept which compares the transformation process of converting input into output. If the occurrence of inefficiency is not totally random, then it should be possible to identify factors that contribute to its existence. In this case, estimating these efficiency measures involves estimating the unknown production frontier: the current state of technology in the industry, representing the maximum output attainable from each input level is called the efficiency frontier.

For these reasons, it is important to analyze the degree to which producers fail to optimize and the extent of any resulting distances from the frontier of full technical efficiency, mainly due to the following reasons:

1. First, only by measuring efficiency, and by separating the associated effects from those of the operating environment, it is possible to explore hypotheses concerning the sources of efficiency, essential to improve performance.
2. Second, efficiency measures are success indicators by which producers are evaluated and the ability to quantify efficiency provides a control mechanism with which to monitor the performance of a production unit.
3. In addition, if policy and planning is to concern itself with the performance of a particular economic unit, it is important to know to what level a given producer may be expected to increase output by simply increasing efficiency, without absorbing any further resources.

Better understanding of the process of generating efficiency requires studying the deeper determinants and factors which explain the differences in efficiency growth.

In response to this most important research issue, and with the increase in data availability, economic literature has shown a resurgence of interest in testing and quantifying various theories of explaining efficiency growth and examining the corresponding relationships has attracted a lot of interest with the main research questions arising could be summarized into:

1. What are the reasons for diverging efficiency?
2. Which factors contribute to efficiency differences?
3. How the efficiency evolves over time, with respect to technical progress and other related determining factors?

This chapter focuses on financial markets, the role of which to the economy is even more important, taking into consideration the slowdown in the world economy, and the effects on the business environment created by the financial crisis. Thus, medium and high technology financial markets have a very important role in creating opportunities making an important contribution to economic growth and development. Nonetheless, financial markets have shortages of different types of resources necessary to develop and implement their strategies. These shortages may include financial, marketing, technological

and managerial resources, or skilled personnel. Overcoming those shortages and increasing technical efficiency has become critical for their long term survival and profitability.

However, due to their nature, these markets are characterized by being very heterogeneous since they differ in their endowments of resources as well as on the risks involved in their productive activities. For this reason, it is of great importance, on the one hand to analyze their efficiency level and potential, and on the other hand, to analyze the factors which determine their efficiency potential. This analysis is the main aim of this chapter, which focuses on the most current innovative methods on estimation of technical efficiency. Thus, this chapter is expected to provide meaningful insights into the level of industry-specific technical efficiency along with factors determining and affecting efficiency. The core aim of this chapter is to understand and evaluate the impact of technical efficiency on productivity and growth and combine the theory (theoretical background) and the empirical applications.

The scope of the suggested chapter is to analyze the process of technical efficiency, plotting both the related present and future trends and developments. Most importantly, this chapter aims to fill the gap in literature regarding the subjects of technical efficiency with respect to the impact of stochastic frontier analysis and data envelopment analysis, two of the most modern and challenging theoretical and empirical approaches. Furthermore, the chapter intends to provide a broad understanding of the current issues and problems of technical efficiency, investigating a great span of aspects and consequences of technical efficiency that are obscure or as yet unexplored. In particular, with its wide range of topics, methodologies and perspectives, the chapter offers stimulating and wide-ranging analyses that will be of interest to students, economic theorists, empirical social scientists, policy makers, as well as the informed general reader.

FOCUS OF THE ARTICLE

In the modern knowledge economy, growth depends extensively on the presence or the formation of a network and environment favorable to innovation, which is based on the endogenous development capabilities. Even though the producer-specific factors are important determinants of innovation activity, technological opportunities and favorable entrepreneurial environment have a positive effect on innovation activity, as well. Technological change, innovation and technology creation and diffusion are an important factor to economic progress.

Combining the production functions in order to create and disseminate innovations leads to improvements in productivity and efficiency. However, at a given moment of time, when technology and production environment are essentially the same, producers may exhibit different productivity levels due to differences in their production efficiency. Within growth process, therefore, efficiency of production resources becomes a critical element in growth, through utilizing the available, yet scarce, resources more productively. Within this framework, productivity represents the estimation of how well a producer uses the available resources to produce outputs from inputs. However, the productivity theory literature has emphasized factors such as productive efficiency, mainly through technological spillovers, increasing returns, learning by doing, and unobserved inputs (e.g. human capital quality), whereas the empirical industrial organization literature has emphasized the degree of openness of countries to imports and industry structure (Koop, 2001).

There is a huge literature on factors influencing productive efficiency and productivity growth. In this literature, it is widely accepted that decision making units are not homogeneous producing units and, therefore, not all units are operating at the same level of efficiency (Caves, 1989).

Bos et al. (2010) investigate the sources of output growth for a panel of manufacturing industries. They propose a flexible model beyond the division of output growth applied in the conventional growth accounting and cross-country growth regression literature, as well as the strong assumptions they typically rely upon (efficient use of resources, constant returns to scale). Bos et al. (2010) focus on the use of technology, the sources of output growth, technology spillovers and catch-up, as well as policy implications. To decrease the aggregation bias that may occur when these issues are considered at the country-level (Bernard and Jones, 1996 a,b), Bos et al. (2010) focus on manufacturing industries. Traditionally, the growth accounting literature has referred to the unexplained part of output growth as the 'productivity residual' or 'technical change'. This interpretation, however, depends, among other things, on the strong assumption that economic units (countries or industries) are always efficient. In reality, however, economic units may well use the best-practice (frontier) technology with varying degrees of efficiency. If this is the case, part of what is measured as technical change is in fact an improved use of the best-practice technology. Put differently, inefficient industries increase output by becoming more efficient in the use of the best-practice technology, whereas efficient industries increase output through technical change. In addition, not controlling for possible inefficient use of inputs may also result in underestimating the productivity of outputs for the best-practice technology. Bos et al. (2010) account for inefficiency and estimate a stochastic production frontier, which is the empirical analog of the theoretical production possibility frontier. This modelling strategy adds structure to the unexplained residual. Under reasonable assumptions, it disentangles the residual into inefficiency and measurement error. Technical change is modelled as a shift of the stochastic frontier, whereas efficiency change is a movement towards or away from the frontier. This framework decomposes output changes into three types of change: technical, efficiency and input change. Empirical literature carries out efficiency analyses along lines similar to Bos et al. (2010), although using different modelling approaches, considering that output change is also decomposed into technical, efficiency, and input change. Even though the attention has largely been at decomposing aggregate (country-level) output, a number of studies have investigated the role of efficiency in explaining growth differentials for a panel of manufacturing industries in the OECD countries (Bos et al., 2010).

As a management tool, stochastic frontier analysis focuses on the variables which are under the decision-makers' control. However, efficiency may be influenced by factors beyond the control of the managers. In stochastic frontier model analysis it is acknowledged that the estimation of production functions must respect the fact that actual production cannot exceed maximum possible production given input quantities.

In stochastic frontier models, output is assumed to be bounded from above by a stochastic production function. In this case, each producer faces a production frontier which is randomly due to stochastic shocks outside the producer's control. Moreover, this method enables to distinguish between shifts in determining factors from movements towards the best-practice frontier. On the other hand, frontier approaches provide a technology frontier constructed by the best-performing producers of the industry. The performance of all producers is then compared against that frontier, which enables the analyst to evaluate each producer's behavior. A frontier function represents a best-practice technology, against which the efficiency of the producers within the industry can be measured (Coelli, 1995). If a producer belongs to the frontier, it is efficient. If a producer is beneath the efficiency frontier, then it is inefficient and further analysis identifies the sources and extent of the inefficiency. There are different alternative methods, in order to estimate this frontier function, as well as to estimate any deviations from it. Literature distinguishes between parametric and nonparametric efficiency measurement and considers the characteristics of each method. Parametric estimation concepts involve strong assumptions about the

functional forms describing the production process or the distribution functions of the stochastic part in the model. Nonparametric approaches assume no parametric restrictions for any features of the probability model and the frontier is not described by a specific analytical function (Acharya and Naqvi, 2012).

Consequently, one of the main questions is to investigate the relationship between inefficiency and a number of factors which are likely to be determinants, and measure the extent to which they contribute to the presence of inefficiency. These factors are neither inputs to the production process nor outputs of it but nonetheless exert an influence on producer performance. Such factors are widely referred to as efficiency explanatory variables.

In this context, the term 'efficiency explanatory variables' is used to describe factors that could influence the efficiency of a producer, where such factors are not traditional inputs and are not under the control of the producer (Fried et al., 1999). However, they may influence productive efficiency. In particular, in order to investigate the determinants of the productive efficiency we distinguish between producers or industry -specific and efficiency explanatory factors (Caves and Barton, 1990).

Efficiency explanatory factors are not under direct control of the producer, at least in the short-run, and they may be industry-affiliated, such as producer location characteristics, managerial restrictions, slow adoption to changes of the market environment and/or to technological developments, or asymmetric information in the labour market, social aspects, geographical or climatic conditions, as well as regulatory and institutional constraints, ownership differences (public/private), and government regulations (Coelli et al, 1998, Stephan et al. 2008). Producer-specific factors, on the other hand, refer to characteristics that can be influenced by the producer in the short-run, as producer size, R&D intensity and degree of outsourcing.

This section connects the discussion of theory in the thesis to the empirics. The empirical analysis focuses on productive efficiency of industries and national economies. In line with the empirical framework based on stochastic frontier analyses (SFA) and data envelopment analyses (DEA), productivity is decomposed into the production possibility frontier and technical (in) efficiency. For this reason, the discussion on theory clearly indicates what should determine the frontier and what affects efficiency.

The empirical methods of frontier and non-frontier production functions were primarily developed to be used for analyses of efficiency mainly across different producers, and not across industries and countries using aggregate data. Such an aggregation across industries and countries may create significant problems because of heterogeneity within the industry or the country. For example, while the production technology can perhaps be assumed to be similar within a given industry, this is not the case when data for different regions, and particularly industries, are pooled. What it is important is to acknowledge the potential problems which it generates and attempt to address these through the empirical methods and framework. Recent contributions include Eberhardt and Teal (2011) and Oh (2012), who demonstrate the serious implications of such aggregation for estimation both of the frontier and efficiency. Empirical estimation should take into consideration that there is likely to be some form of aggregation bias. As also becomes apparent from the analysis by Oh (2012), if SFA approach is used for the same industries and countries, but in one case aggregate industry-level data is used, and in another firm-level data is used, the results will be different. This is meant to show the impacts of aggregation bias, on the basis, that firm-level data adds up to the industry-level but smooths out firm-level heterogeneity (Ferreira and Souza, 2015 and Rahim, et al, 2013).

Stochastic frontier studies often employ aggregate data to analyse the productivity and technical efficiency of regions. According to Oh (2012), a stochastic frontier model is run on plant-level data and region-level aggregate data. Comparisons of estimated coefficients and characteristics of regional produc-

tion based on estimation outcomes suggest that an empirical model employing regional-level data can provide misleading results concerning the production function faced by a representative plant in a region.

Measurements of inefficiency in financial markets were first constructed by estimating deterministic frontiers and subsequently by using stochastic frontiers. Aigner and Chu (1968) were the first researchers to estimate a deterministic frontier using Cobb-Douglas production function through linear and quadratic programming techniques. They argued that for a given industry producers might differ from each other in their production processes (Covitz et al, 2013 and (Dharmendra and Fida, 2015).

The distinguishing features among producers could be represented by:

1. attained values for certain technical parameters in an industry production function,
2. differences in scales of operation, and
3. various structures in their organization

As far as the research implementing technical efficiency analysis is concerned, there is a great number of papers examining technical efficiency through stochastic Frontier Approach or Data Envelopment Analysis. Camanho and Dyson (2005) enhanced cost efficiency measurement methods to account for different scenarios relating to input price information in banking industry. These consist of situations where prices are known exactly at each decision making unit (DMU) and situations with incomplete price information. The assessments under price uncertainty are based on extensions to the Data Envelopment Analysis (DEA) model that incorporate weight restrictions of the form of input cone assurance regions. Huang and Wang (2002) estimated economic efficiency and economies of scale, using panel data of 22 Taiwanese commercial banks over the period 1982-97, employing a wide range of parametric and non-parametric cost frontiers' efficiency estimation methods to estimate economic efficiency and economies of scale, using the same panel data of 22 Taiwanese commercial banks over the period 1982-97. According to their empirical implementation, the two methodologies yield similar average efficiency estimates, yet they come to very dissimilar results pertaining to the efficiency rankings, the stability of measured efficiency over time, the consistency between frontier efficiency and conventional performance measures, and the estimates of scale economies. Thus, the choice of an estimation approach can result in very different conclusions and policy implications regarding cost efficiencies and cost economies. These findings suggest that making policy decisions and evaluations relies on multiple techniques and specifications (Apergis, 2014 and Berger and Bouwman, 2016).

Silva Portela and Thanassoulis (2005) using parametric and non-parametric methods, have been focusing mainly on profit efficiency and to identify the sources of any shortfall in profitability (technical and/or allocative inefficiency). The method is applied to a set of Portuguese bank branches first assuming long run and then a short run profit maximisation objective. In the long run most of the scope for profit improvement of bank branches is by becoming more allocatively efficient. In the short run most of profit gain can be realized through higher technical efficiency. Wheelock and Wilson (2000) use alternative measures of productive efficiency to proxy management quality in individual U.S. banks, and find that inefficiency increases the risk of failure while reducing the probability of a bank's being acquired. Becchetti and Sierra (2003) investigated the determinants of bankruptcy in three representative unbalanced samples of Italian firms for the periods 1989-91, 1992-94 and 1995-97. Two important results are that: (i) the degree of relative firm inefficiency measured as the distance from the efficient frontier has significant explanatory power in predicting bankruptcy (ii) qualitative regressors such as customers' concentration and strength and proximity of competitors have significant predictive power.

In order to promote innovation activities and technological opportunities entrepreneurship enhancement seems to have a significant importance not only to business success, but also to the long run performance of the economy as a whole. Under this perspective, growth policies should focus on creating favorable environment for the co-operation between banks and institutions that support the development and exploitation of knowledge and innovation.

Furthermore, policies should promote the entrepreneurial relations between firms and institutions, fostering the development and dissemination of the expertise, the mobility of human and physical capital and the enhancement of the relationships between business and research entities. Specifically, they should encourage actions such as, promoting innovation, technology transfer and interactions between firms and higher education and research institutes, networking and industrial co-operation and support for research and technology supply infrastructure.

As it has already been mentioned, innovation and technology is an important source of regional competitiveness through facilitating cooperation between the various parties involved in both the public and private sectors. In particular, they can improve collective processes of learning and the creation, transfer and diffusion of knowledge and transfer, which are critical for innovation. Such cooperation and the networks that are formed help to translate knowledge into economic opportunity, while at the same time building the relationships between people and organizations which can act as a catalyst for innovation. Such actions should extend to all the policy areas relevant for economic, scientific and social development and should ideally establish a long-term policy horizon. This, however, needs to happen not just in central parts where productivity and employment are highest and innovative capacity most developed but throughout the Union. Countries and regions need assistance in overcoming their structural deficiencies and in developing their comparative advantages. This means, among others, that encouraging the development of knowledge-based economic activities and innovation and that particular attention needs to be given to:

1. developing new innovation promotion policies which focus much more on the provision of collective business and technology services to groups of firms which can affect their innovative behaviour, rather than direct grants to individual firms which tend only to reduce costs temporarily.
2. developing new policies to strengthen the capacity of SMEs to innovate through business networks and clusters and improving their links with the knowledge base, including with universities and research centres.
3. encouraging the development of the indigenous R&D potential of weaker regions and their capacity to adapt technological advances made elsewhere to local circumstances and needs.
4. facilitating access of researchers, businesses and others in less favoured regions to international networks of excellence, sources of new technology and potential R&D partners.

These conditions are largely related to economic competitiveness and include, among others, the capacity of a regional economy to generate, diffuse and utilize knowledge and so maintain an effective regional innovation system. Furthermore, policies should promote the entrepreneurial relations between firms and institutions, fostering the development and dissemination of the expertise, the mobility of human and physical capital and the enhancement of the relationships between business and research entities. Specifically, they should encourage actions such as, promoting innovation, technology transfer and interactions between firms and higher education and research institutes, networking and industrial co-operation and support for research and technology supply infrastructure. Such cooperation and the networks that are formed help to translate knowledge into economic opportunity, while at the same time

building the relationships between people and organizations which can act as a catalyst for innovation. Such actions should extend to all the policy areas relevant for economic, scientific and social development and should ideally establish a long-term policy horizon.

Under this perspective, growth policies should focus on creating favorable environment for the co-operation between firms and institutions that support the development and exploitation of knowledge and innovation. Furthermore, policies should promote the entrepreneurial relations between firms and institutions, fostering the development and dissemination of the expertise, the mobility of human and physical capital and the enhancement of the relationships between business and research entities. Specifically, they should encourage actions such as, promoting innovation, technology transfer and interactions between firms and higher education and research institutes, networking and industrial co-operation and support for research and technology supply infrastructure. These conditions are largely related to economic competitiveness and include, among others, the capacity of a regional economy to generate, diffuse and utilize knowledge and so maintain an effective regional innovation system, contributing into a sustainable economic growth path.

However, the main concern of an industry or country in its innovation policy should be to have the optimal combination of business activities in various stages of the innovation cycle. Countries, industries, or firms concerned primarily with activities of the innovation takeoff stage may find themselves lacking sufficient economic resources to exploit these activities through improvement-related innovations. Countries, industries, or firms dominated by activities of the maturation stage, such as limitation and improvement of given technologies, incremental innovation, diversification of products, exploitation of scale economy, extension of vertical integration, and automation of production processes, will lose their advantage with respect to dynamic efficiency and experience stagnation (Haustein, et al., 1981). Without knowing the needs of and possibilities offered by the economic environment, one cannot understand the mechanism of technological change towards productivity enhancement. A crucial task to improve innovation policy at the national and industrial levels is to provide information about fields of innovation, which are dependent on factors which fall into three categories:

1. Urgency of demand for the innovation
2. Existence of scientific and technological advancements
3. Existence of a socio-economic environment which allows productive efficiency enhancement through scientific and technological feasibilities

Successful producers will probably be those able to respond effectively in these fields. Once the right direction is chosen, success depends on managing the factors that influence innovative activities towards efficiency enhancement.

SOLUTIONS AND RECOMMENDATIONS

Nowadays, the role of manufacturing industries to the economy is even more important taking into consideration the slowdown in the world economy, and the effects on the business environment created by the financial crisis. Thus, manufacturing industries have a very important role in creating opportunities making an important contribution to economic growth and development. However, due to their nature, manufacturing industries are characterized by being very heterogeneous since they differ in their endowments of resources as well as on the risks involved in their productive activities. For this reason, it is

of great importance, on the one hand to analyze their efficiency level and potential, and in addition, to analyze the factors which determine their efficiency potential. Thus, this thesis provided insights into the level of industry-specific technical efficiency along with factors affecting inefficiency, focusing on manufacturing industries and seeks to obtain the empirical results by specifying the translog functional form and the model for the technical inefficiency effects in the stochastic frontiers.

The key factors influencing the competitiveness of the EU manufacturing industry are access to innovation, R&D and international trade. The main recommendations revolve around three key areas innovation and research and strengthening networks and clusters; responsible use of natural resources; and the need for open world markets with fair competition. Clustering, collaboration and the formation of strategic alliances are becoming increasingly important. Continuous R&D and innovation efforts are essential elements into guaranteeing the long-term competitiveness of Europe's manufacturing industries. European research, technical development and innovation policies should focus on developing the framework conditions that stimulate innovation, entrepreneurship and, thus, growth and employment. Innovation for sustainable manufacturing requires paying attention to the interfaces between R&D policies with other critical policy fields. Strong emphasis needs to be placed upon the management of the interfaces between R&D policy and other policy realms competition policy, intellectual property rights, standardization, education and training, environmental policy, labour market, employment and social policy, to facilitate the creation of a sustainable European manufacturing industry environment, along with fiscal instruments and incentives. Understanding future challenges and issues is important on future developments in manufacturing. Industrial change driven by new technological opportunities will impact on the manufacturing structures in European Union. contribute to sustainable growth and improve technical efficiency.

Finally, technical progress is another major determinant as new technologies allow the automation of production processes that have led to many new and improved products. allow for better and closer links between firms. and can help improve information flows and organization of production. At the same time, technical progress can be embodied in new equipment and trained workers can only be fully productive if they have the appropriate equipment with which to work. Increases in physical capital are clearly necessary as there are spillovers from capital investment to productivity growth. Thus it is not appropriate to consider physical capital, human capital and technology as separate factors since their contributions are closely linked. It is the combination of these three factors and the way in which they are organized and managed within the industry that will determine the extent of productivity growth. For sustained output growth, it is also important that a balance between the three main factors be maintained.

The potential for technical efficiency enhancement is considered to a large extent to depend on the EU's capability to transform the economy towards one that makes more productive use of its resources. Much will depend on the capacity of markets to facilitate the reallocation of resources to industries that show rapid productivity growth. However, it is difficult to predict which industries will be the most productive in the future, as technology and innovation trends are inherently difficult to forecast. For now, a productive use of a larger input from skilled employment and the exploitation of ICT investments in manufacturing industries appear the most successful policy avenues for a European productivity revival.

Promoting technical and productive efficiency into the European Union has resulted in a growing challenge for policymakers. Productive and regional disparities and inequalities are an increasing issue for the European Union to consolidate, as a result policy makers have to adapt the policy agenda considering industrial and innovation policy in order to enhance technical and productive efficiency capabilities.

Moreover, efficiency and policy planning is a major matter which due to the wide interpretations and implications should have a clear mix of principles and priorities, mainly focusing on the effectiveness

of the related EU policies. EU industrial and innovation policy should aim to bridging the technical efficiency gaps, both in industrial and country level, benefiting for economic cohesion, allowing members states with a backwards economy or backwards industries to modernise and thus compete in European and international markets, promoting convergence, competitiveness and cooperation. Infrastructure, innovation and investments should be among the main goals.

FUTURE RESEARCH DIRECTIONS

As it has been asserted above, globalization and worldwide competition has shifted the comparative advantage of corporations and economies towards the factor of knowledge and innovation, where entrepreneurship based on the technical efficiency enhancement plays a rather important role, as far as the growth, productivity and competitiveness enhancement are concerned. In order to promote innovation activities and technological opportunities entrepreneurship enhancement seems to have a significant importance not only to business success, but also to the long run performance of the economy as a whole. Under this perspective, growth policies should focus on creating favorable environment for the co-operation between firms and institutions that support the development and exploitation of knowledge and innovation and technical efficiency. Furthermore, policies should promote the entrepreneurial relations between firms and institutions, fostering the development and dissemination of the expertise, the mobility of human and physical capital and the enhancement of the relationships between business and research entities. Specifically, they should encourage actions such as, promoting innovation, technology transfer and interactions between firms and higher education and research institutes, networking and industrial co-operation and support for research and technology supply infrastructure.

Regarding further research, special focus should be put on the appreciation of the ways in which organizations, industries and industries change and adapt in the presence of new opportunities and constraints. Accordingly, future research could study how changing configurations of the knowledge based economy combined with the emergence and adaptation of institutional structures in an technology-intensive industry like manufacturing industries, especially these of high technology and high value added. In particular, a dual evolutionary research could be undertaken regarding the growth in ICT investment in the industry and the emergence of knowledge communication across countries. In doing so, it highlights the coordinating role of ICT technologies and economy openness in enabling the innovative potential opened up by new technologies and innovation activities.

CONCLUSION

After the US subprime crisis, the first signs of a sovereign debt crisis spread among European financial players. The regulation of the markets by European Commission and European Central Bank created limitation to obtained great amount of liquidity in commercial banking sector. In this context, the successful survival of some European banks became in a dangerous situation.

For this reason, financial researchers had dedicated a large effort to discover the factors that explain differences in the enterprises' financial performance during several years. Around the world stock markets have fallen, large financial institutions have collapsed or been bought out, and governments in even the wealthiest nations have had to come up with rescue packages to bail out their financial systems. In this context, all agents focus their attention on productivity and efficiency gains since both are central to the

growth of firms in any industry. For this matter, inefficiency can be due to structural problems or market imperfections or even other factors, resulting in firms producing below their maximum attainable output.

Efforts to measure how efficiently a firm (a Decision Maker Unit, known as DMU in literature) produces outputs with its inputs have led to the development of a number of efficiency concepts, including scale efficiency, scope efficiency, economic efficiency, and technical efficiency (Ferreira and Souza, 2015)

This chapter aims to investigate the degree of technical efficiencies in financial sector, by using the data envelopment analysis (DEA) and stochastic frontier approach (SFA). The results related to returns-to-scale emphasize that decreasing returns-to-scale is the major form of scale inefficiency. The estimated efficiency scores could be further regressed (e.g. using Tobit model) on a set of explanatory variables, i.e. size, profitability, capital adequacy and liquidity.

Financial sector plays an important role in the growth and stability of an economy. It helps in channelizing the household savings to corporate and industries where it is optimally used for the development of the country. Therefore, financial institutions work as an intermediary and if this financial intermediation is efficient it is going to add value to economy as a whole. Thus, the performance of the financial system is important and is a point of concern for all the stakeholders. The performance measurement is of prime importance for all the economies. Performance of financial sector can be measured either by using financial ratios or by measuring its efficiency. Efficiency is defined as ratio of output and input of the firm. Proper and efficient utilization of resources or inputs to get desired quantity and quality of output is always expected by the management.

As compared to past, today financial industry is facing a tough competition and the probability of bankruptcy is also high as the financial markets across the world are integrated. Because of integration, risk in one part of the world is easily transmitted to rest of the countries. In this uncertain scenario, it is essential to measure the technical efficiency of the sector. The present study is an attempt to quantify the degree of overall technical efficiency and detect the source of inefficiencies either in management or in handling resources used to run an organization. The measure of scale efficiency provides the ability of the management to choose the optimum size of bank or, to choose the scale of production (Dharmendra and Bashir, 2015).

As it has already been mentioned, innovation and technology is an important source of regional competitiveness through facilitating cooperation between the various parties involved in both the public and private sectors. In particular, they can improve collective processes of learning and the creation, transfer and diffusion of knowledge and transfer, which are critical for innovation. Such cooperation and the networks that are formed help to translate knowledge into efficiency opportunities. Such actions should extend to all the policy areas relevant for economic, scientific and social development and should ideally establish a long-term policy horizon. This, however, needs to happen not just in central parts where productivity and employment are highest and innovative capacity most developed but throughout the Union. Countries and regions need assistance in overcoming their structural deficiencies and in developing their comparative advantages. This means, among others, that encouraging the development of knowledge-based economic activities and innovation and that particular attention needs to be given to:

- developing new innovation promotion policies which focus much more on the provision of collective business and technology services to groups of firms which can affect their innovative behaviour, rather than direct grants to individual firms which tend only to reduce costs temporarily.
- developing new policies to strengthen the capacity of SMEs to innovate through business networks and clusters and improving their links with the knowledge base, including with universities and research centres.

- encouraging the development of the indigenous R&D potential of weaker regions and industries and their capacity to adapt technological advances made elsewhere to local circumstances and needs.
- facilitating access of researchers, businesses and others in less favoured regions to international networks of excellence, sources of new technology and potential R&D partners.

These conditions are largely related to productive and technical efficiency and include, among others, the capacity of a regional economy to generate, diffuse and utilize knowledge and so maintain an effective production system.

Towards this direction, our expected contribution is considered providing a better understanding of the contribution of technical change; ICT investment, innovation activities and economy openness to technical efficiency taking into account the interrelationships and the complementarities between innovation and efficiency. This chapter investigated various aspects of the relationship between productive efficiency and determining factors in an attempt to reach a better understanding of the contribution of alternative factors to technical efficiency growth. Industries should investigate and act towards identifying, developing and deploying their resources that may influence their technical efficiency, competitiveness and consequently their productivity performance, with better identification and understanding of the key resources, mainly increased knowledge about the impacts of different determining factors on technical efficiency.

KEY TERMS AND DEFINITIONS

Decision-Making Units: The decision-making unit (DMU) is a collection or team of individuals who participate in a buyer *decision* process.

Determining Factors: A factor is one of the things that affects an event, decision, or situation.

Efficiency: Efficiency is a measurable concept, quantitatively determined by the ratio of useful output to total input.

Financial Markets: A financial market is a broad term describing any marketplace where trading of securities including equities, bonds, currencies, and derivatives occur. Some financial markets are small with little activity, while some financial markets like the New York Stock Exchange (NYSE) trade trillions of dollars of securities daily.

Productive Efficiency: Productive efficiency is concerned with producing goods and services with the optimal combination of inputs to produce maximum output for the minimum cost. To be productively efficient means the economy must be producing on its production possibility frontier.

Technical Efficiency: Technical efficiency is the effectiveness with which a given set of inputs is used to produce an output. A firm is said to be technically efficient if a firm is producing the maximum output from the minimum quantity of inputs, such as labour, capital, and technology.

Financing Digital Innovation for Sustainable Development

1

Danilo Piaggese <https://orcid.org/0000-0003-4610-174X>*Knowledge for Development (K4D), USA***Helena Landazuri***Knowledge for Development (K4D), USA*

INTRODUCTION

The United Nations' Sustainable Development Goals (SDG) 17 (SDG 17), supports “access to science, technology and innovation and enhance knowledge sharing ... through improved coordination among existing mechanisms, at the United Nations level” ([United Nations, ECOSOC, Metadata Statistics website](#)). SDG 17 pursues capacity building through improved access to data (i.e. solid statistics), information and knowledge to support decision-making and oversight. SDG17 is also closely linked to Objective 6, which covers the provision of technical knowledge, quality and services. Such guidelines embrace the economic viability, replicability and sustainability attributes that innovation must have to be called such, in the field of promoting digital innovation. Those guidelines provide a clear path to streamline efforts in this area by directing support to three crucial areas: (i) developing a market for digital innovation products and services; (ii) supporting initiatives to bring about new and more efficient business models and processes; and (iii) providing focused support to the generation of innovative products and services. To achieve these ends, it is proposed to establish adequate mechanisms to provide technical and financial support in each one of those areas, utilizing partners and collaboration mechanisms.

In this context, the authors propose two different Digital Innovation Trust Funds financing innovation for sustainable development, reviewing other funds and funding sources with similar or complementary purposes that operate at international development agencies.

The specific nature and workings of the financial instruments is discussed in detail and defined further, presenting two proposed scenarios for the Inter-American Development Bank (IADB) and the Food and Agriculture Organization of the United Nations (FAO), two of the largest international organizations working for the development of emerging economies in general, and the achievement of the SDGs in particular.

BACKGROUND

Main observations from success and failure stories from other donors as well as lessons learned in the implementation of innovation funding in developing countries include (Piaggese, 2017):

- a. International development agencies are all consistently pursuing the overall goal of reducing poverty and promoting socio-economic growth, under the guidance of the UN's Sustainable Development

DOI: 10.4018/978-1-7998-3473-1.ch007

- Goals. For that overarching goal, digital innovation, ICT for development and technology innovation are means to achieve those goals faster, more efficiently and more widely; while they do not appear as a sector or priority activity, they are present in practically each sectoral effort and project. It is possible to say that today, digital innovation has been mainstreamed into development financing.
- b. Innovation funding tends to be directed towards financing: (i) applications of ICT to make more efficient and reach wider audiences for sector projects, with emphasis on education, health, transportation, environment, among others; (ii) applications of ICT to increase the amount, relevance and quality of information available to beneficiaries, in order to improve decision making; (iii) e-government and government capacity building; (iv) government digital strategy development; (v) knowledge acquisition, development, and management.
 - c. Financing for basic or applied research is less common; responsibility for this type of investment is left to government intervention, if any. In practice, research and development rest with large private corporations mostly in developed countries.
 - d. Financing in support of private sector investment is rare; some investment is present for private sector (mostly small & medium enterprises) capacity building, but risk capital or equity investment is extremely rare. Identified sources of development (concessionary) financing in development countries are limited to multi-lateral banks and a couple of bi-lateral financial institutions. Financing for initial stages of product or service development (start-ups) is even less frequent, with only a handful of sources available.

THE INTER-AMERICAN DEVELOPMENT BANK (IADB)

The Knowledge Economy (KE) is an interconnected, globalized economy where knowledge resources such as know-how, expertise and intellectual property are as critical as other economic resources such as land, natural resources, or even manpower (Piaggese, 2009). Under this concept, Knowledge is recognized as a source of competitiveness, where value lies in innovative ideas, services and networks, using technology as an instrument, not as an end. The KE is not a subject per se, but rather a new development paradigm where education, information and communication technologies and infrastructure, innovation, social inclusion and intellectual property rights protection converge into a “virtuous” circle to transform the intangible nature of Knowledge into an asset with market value able to contribute substantially to economic growth.

While Asia has excelled in developing knowledge-based industries (OECD, 2000) and knowledge-rich products, Latin America and the Caribbean (LAC), in general, lag well behind other developing countries. The experience of Asia shows that the successful transition to a KE typically involves long-term investment in education, development of indigenous innovation capabilities, modernization of information sharing infrastructure, and creation of a market environment that is conducive to knowledge-based-transactions. It is estimated that the LAC region’s performance for the education and ICT related indicators is somewhat below the average for all developing countries (Trucano, 2005); while indicators for institutional quality and innovation indicators are generally weaker.

International development organizations are striving to introduce Knowledge as an investment category to help countries find a suitable and viable niche in the international and national markets where Knowledge is a tradable asset. By establishing two closely related funding mechanisms to support this purpose, the Inter-American Development Bank (IADB), the largest development bank in the LAC region, would provide technical assistance for beneficiary countries to find such niche and then develop

the instruments to derive income generation opportunities from it. Both Knowledge Economy Funds will provide non-reimbursable resources to trigger the adoption of KE principles and practices among its borrowing member countries.

Individually or collectively, LAC countries would greatly benefit from the regional production and use of Knowledge and its world-wide exchange as a tangible asset and commodity. The IADB would make a substantial contribution by assisting its borrowing member countries in finding niches that respond to their comparative advantages and in setting up the structures and infrastructure needed to participate effectively in this competitive market.

The knowledge-driven economy has highlighted the growing importance of knowledge for industrial structure, for national economic performance, and for sources of competitive advantage for both firms and nations. A challenge has emerged for governments to build national capabilities, facilitate collaboration within and between businesses, and encourage competition. In this new economy, sustained use and creation of Knowledge are at the center of the economic development process. Knowledge and education can be treated as a business product, as educational and innovative intellectual products and services can be exported for high value return as productive assets. In a KE, Knowledge is used to produce economic benefits, therefore making it an engine of economic growth. KE, thus, is defined as the added non-monetary value that society accrues from increased access to data, information, and knowledge in the new, globally connected world (Piaggese, 2009).

Today an un-quantified amount of Knowledge is lost because development agents are not actively seeking to capture and retain it (The Competency Group, 2018). People's knowledge is lost when employees move on; indigenous knowledge is often disregarded when modern technology is introduced; institutional knowledge is drained when changes overrun existing operating systems; cultural knowledge is wasted when development goals are narrowly defined as economic gain. In most of the world, Knowledge is not yet considered a commodity to be exchanged and thus its impact on today's "knowledge society" is grossly underestimated.

A significant gap exists today between developed and developing countries in terms of access to the potential benefits of the KE (United Nations, 2000). Least developed countries are at a great disadvantage because international trade and direct external investment flows do not favor them. Furthermore, trademark and intellectual property right systems are not well developed and do not adequately protect the smaller economies.

In their efforts to tap the benefits of the KE, developing countries would need to consider action in two fronts. On the one hand, investment is needed to capture, retain and manage knowledge that already exists (so called "knowledge spillover") and put it to work as a factor in production, a tradable good or a negotiation chip. Here the LAC region can be expected to have significant advantages, since LAC countries are particularly well endowed in terms of vernacular, traditional and original knowledge. On the other hand, developing countries must at the same time invest in the generation of new knowledge through investments in education, innovation, adequate regulatory framework and viable institutions. It is possible that some countries would choose one path or the other, or that some may choose to undertake these paths sequentially.

In either case, the transition towards a KE requires that the rules and practices that determine success in the industrial economy be rewritten. Economic valuation and accounting rules need to be redefined so that governments, industries and organizations incorporate the value of knowledge and the added value that its innovative use would create. Accordingly, public policies must be redesigned to provide the conditions necessary to make knowledge a monetary asset. Public policies designed and implemented to support the knowledge economy must focus on how to generate public value out of knowledge exist-

ing or produced in the country, and how to make locally available knowledge produced in the global economy. Public policies must therefore provide conditions to exploit the positive externalities of the global knowledge economy.

The concept of KE does not necessarily revolve around high technology or ICT (information and communication technologies). Its instruments do not need to be technological. Sometimes, utilization of traditional means to collect, transmit and apply knowledge may be more effective than highly sophisticated systems. The experience of Asia, which precedes the rest of the world in this path, shows that the successful transition to a KE typically involves long-term investment in education, development of indigenous innovation capabilities, modernization of information sharing infrastructure, and creation of a market environment that is conducive to knowledge-based-transactions.

The World Bank and other international financial institutions that are active in this field recognize the following elements as pillars and framework of the KE (Chen, Derek & Carl J. Dahlman, 2006):

- a. Economic incentives and institutional regime —i.e. economic policies and institutions that permit efficient mobilization and allocation of resources stimulate creativity and the dissemination and use of existing knowledge;
- b. Educated and skilled workers —i.e. a labor force that continuously upgrades and adapts its skills to efficiently create and use knowledge;
- c. An innovative institutional and entrepreneurial system —i.e. private firms, research centers, universities, consultants and other organizations actively involved in keeping up with the knowledge revolution tap into the growing stock of global knowledge, assimilating and adapting it to local needs;
- d. A modern and adequate information infrastructure —i.e. means to effectively acquire, process, communicate and disseminate information and knowledge.

Investments in activities that bring about these conditions are necessary to sustain the creation and adoption of knowledge as a factor in domestic economic production. Sustained use of knowledge leads to higher value-added goods and services. This in turn results in greater probability of economic success, and hence, greater and sustainable economic development. Knowledge can make an enormous difference in a country's position within today's highly competitive and globalized world economy.

National and international development organizations are striving to make their operational development methodologies with beneficiary countries more effective. An important part of this effort will depend on how well the role of knowledge is understood and integrated into the development process.

The conditions required to develop a KE are numerous and complex. Multi-lateral Development Banks (MDBs)' clients expect excellence in the provision of services and the use of state-of-the-art methods and technology to improve the impact of their development investment. There is an un-met demand for knowledge products among the MDBs' borrowing member countries. In several cases, access to knowledge-rich products is more important to a country than investment capital.

Most of international financing institutions are striving to help developing countries enter the KE "market", acknowledging the promise the KE holds for those which find a competitive niche in it. We see mechanisms to provide rapid and effective response to the demand for knowledge products; notwithstanding, the MDBs would need to make a concerted effort to develop and apply the requisite instruments needed to optimize KE benefits for its clients, through an activity completely and exclusively focused on this purpose.

Among the MDBs, the Inter-American Development Bank (IADB) is the oldest and leading development bank in the LAC region. For this reason, two funding instruments are proposed for the IADB to engage the KE sector. The first would involve ordinary capital non-reimbursable funding (IADB KE-Fund) which would support all actions needed to place the Bank as a proactive, agile and innovative strategic partner for the Bank's borrowing member countries in their search for a viable niche in the international KE markets. The IADB KE-Fund would finance high-level government advice and technical assistance, country-specific analysis, financial surveys, market studies and other non-financial products, as well as pilot projects required to support beneficiary countries. The IADB-KE Fund would also act as leverage to induce other donors to channel funds towards the LAC region in support of KE projects, by acting as a matching-fund source to its sister fund, the Multi-Donor KE Fund. The second instrument is a Multi-Donor KE Fund, which would focus on technical cooperation and pre-investment for KE project financing, including providing funds for pilot or demonstrative projects.

Through these two funds the IADB would provide borrowing member countries with incentives and tools to use their knowledge capital and generation capabilities as well as to get access to knowledge created in most advanced economies and put it to work towards their development. The IADB's value added would be to facilitate each country in finding its own niche and identifying investments that would facilitate the development of their Knowledge sector and exploit the relevant knowledge related sources publicly available in the global knowledge economy. The implementation of these funds would also affect positively existing IADB units directly, to the extent that it would introduce KE related investments in their portfolios.

A PROPOSED IADB FUND FINANCING DIGITAL INNOVATION FOR SUSTAINABLE DEVELOPMENT

The authors present a scenario for the establishment of an IADB-KE fund. The objectives of the proposed IADB-KE Fund are: (i) provide timely knowledge-rich technical assistance demanded by beneficiary countries in the various sectors that make up the Bank's portfolio; (ii) support the development of KE policies and strategies in beneficiary countries; (iii) develop a new generation of KE technical assistance and investment portfolio for the Bank, jointly with the Multi-Donor KE Fund; and (iv) establish the IADB at the forefront of international development organizations in this field.

All borrowing member countries of the Bank are potential beneficiaries of the IADB KE Fund. However, the Fund would start with a few participating selected countries based on interest expressed by their authorities. In each of those countries, local authorities need expressing their official support for the Fund proposal and have advanced letters of interest to become part of the first group and gain access to technical cooperation to prepare their respective project proposals. Other countries would be added to the list as the Fund initiates operations and has access to resources that would allow the development of additional project proposals.

Eligible beneficiaries would include: (i) public sector agencies; (ii) universities and all higher-level learning agencies, whether public, semi-public or private; (iii) research and development agencies and centers of excellence, public, semi-public or private; (iv) private sector organizations; and (v) non-governmental, non-for-profit organizations, devoted to social purposes.

The IADB KE-Fund would fund, on a non-reimbursable basis, the following expenditures: (i) consulting services to advise governments on strategic thinking and planning to harness the benefits of the KE within their individual circumstances and priorities; (ii) consulting services required by sector Divisions

and beneficiary countries to improve sector knowledge in any sector attended by the Bank; (iii) technical cooperation to define KE development strategies, policies, and plans; (iv) knowledge sharing and cross-fertilization events to facilitate intra-region discussion of opportunities, restrictions and common ground; (v); studies to analyze market developments, trends, lessons learned, conceptual developments and other subjects that would advance the Bank's positions and capabilities in this field; (vi) evaluation of progress and impact of the Fund and dissemination of results; and (vii) match the funding provided by the Multi-Donor KE Fund for KE demonstration and start-up or pilot projects identified by either Fund.

Indeed, to the extent that it is aimed at contributing to making the Bank a knowledge creation and capacity building institution, the Fund activities are consistent with this purpose. The Fund would include costs associated to the delivery of the Fund activities, including Fund staff salaries, benefits and overhead costs, as well as Fund staff participation in inter-agency coordination meetings where the Bank can learn from other agencies' work or share results from its own experience as well as Project related and promotional travel.

Application of KE opportunities directed towards making more profitable and equitable utilization of existing or new knowledge would hold exciting potential to improve the conditions of lower-income groups. Through carefully crafted KE investments, the poor can earn more out of their knowledge capital than they would out of their labor alone. Socio-economic benefits of KE projects could include, for example: employment derived from new knowledge-based industries; higher education institutions aligned with KE objectives and niches; preservation and valorization of traditional knowledge; or income generation opportunities associated to new cultural industries. Thus, a line of funding devoted to providing the poor with the option and means to participate in the KE would contribute enormously to the growth in value and worth of low-income groups and society in general.

On the other hand, multiplier effects can be achieved from industry's incursion in the KE field, through new knowledge development or better management of existing knowledge. Local industries able to locate a niche where they can compete favorably in international markets through development of new knowledge-based applications would also benefit from direct project investment, as well as from improved national policies designed to provide incentives and facilitate their insertion in such competitive markets that the Fund would promote.

Direct beneficiaries of KE investment would include: (i) public sector institutions from any sector where gains can be attained by the application of KE instruments; (ii) academic and training institutions that can establish centers of excellence for the diffusion of KE in the LAC region; (iii) private sector companies and foundations who are willing to invest their own resources matching those of the Bank for the pursuit of joint objectives; and (iv) communities where KE projects are directed to raise employment or training opportunities.

THE FOOD AND AGRICULTURE ORGANIZATION OF THE UNITED NATIONS (FAO)

FAO's Reviewed Strategic Framework and Outline of the Medium Term-Plan 2018-21 of December 2016 (FAO, 2016) embraced the United Nations' Sustainable Development Goals (SDGs) as guiding objectives for its own results framework and work program, with emphasis on the fulfillment of SDG2 "End hunger, achieve food security and improve nutrition and promote sustainable agriculture". SDG 17 supports "access to science, technology and innovation and enhance knowledge sharing ... through improved coordination among existing mechanisms, at the United Nations level" (United Nations, idem).

In the Reviewed Strategic Framework, SDG 17 was mentioned in support of all FAO's Five Strategic Objectives as it pursues capacity building through improved access to data (i.e. solid statistics), information and knowledge to support decision-making and oversight. SDG17 is also closely linked to Objective 6, which covers the provision of technical knowledge, quality and services in support of all crosscutting themes that underlay all Five Strategic Objectives.

To contribute to the fulfillment of FAO's Strategic Framework, the institution spearheaded the development of a Digital Strategy (FAO, 2017), which aims at taking advantage of new digital technologies to support FAO's mission. Such new digital technologies have the potential to accelerate FAO's meeting its strategic objectives, making use of its knowledge capital, becoming more competitive in the process. Derived from the Digital Strategy's Action Plan, FAO is to develop a systematic approach to innovation, defining innovation as "The process of translating an idea or invention into a good or service that creates value or for which customers will pay. To be called an innovation, an idea must be replicable at an economic cost and must satisfy a specific need." To implement this, the Digital Strategy consists of the following priorities: implement specific projects where IT solutions is the prime driver; use partnerships to deliver measurable results; and establish an innovation fund to encourage a culture of innovation, all the time providing for adequate oversight and evaluation.

Guiding the implementation of the Digital Strategy, tactical guidelines were issued, in the document "Implementing digital innovation at FAO" (Varas, 2017). Such guidelines embrace the economic viability, replicability and sustainability attributes that innovation must have to be called such at FAO particularly in the field of promoting Digital Innovation. Those guidelines provide a clear path to streamline FAO's efforts in this area by directing its support to three crucial areas: (i) developing a market for digital innovation products and services; (ii) supporting initiatives to bring about new and more efficient business models and processes; and (iii) providing focused support to the generation of innovative products and services. To achieve these ends, the authors propose to establish adequate mechanisms to provide technical and financial support in each one of those areas, utilizing partners and collaboration mechanisms.

In designing this proposal for an Innovation Trust Fund, the authors have investigated other Funds and funding sources with similar or complementary purposes that operate at other international agencies. Main observations derived from this exercise include (Piaggese, 2017. Idem):

- a. International development agencies are all consistently pursuing the overall goal of reducing poverty and promoting socio-economic growth, under the guidance of the UN's Sustainable Development Goals, just as FAO does. For that overarching goal, digital innovation, ICT for development and technology innovation are means to achieve those goals faster, more efficiently and more widely; while they do not appear as a sector or priority activity, they are present in practically each sectoral effort and project. It is possible to say that today, digital innovation has been mainstreamed into development financing.
- b. Innovation funding tends to be directed towards financing: (i) applications of ICT to make more efficient and reach wider audiences for sector projects, with emphasis on education, health, transportation, environment, among others; (ii) applications of ICT to increase the amount, relevance and quality of information available to beneficiaries, in order to improve decision making; (iii) e-government and government capacity building; (iv) government digital strategy development; (v) knowledge acquisition, development, and management.
- c. Financing for basic or applied research is less common; responsibility for this type of investment is left to government intervention, if any. In practice, research and development rest with large private corporations mostly in developed countries.

- d. Financing in support of private sector investment is rare; some investment is present for private sector (mostly small & medium enterprises) capacity building, but risk capital or equity investment is extremely rare. Identified sources of development (concessionary) financing in development countries are limited to multi-Lateral banks and a couple of bi-lateral financial institutions. Financing for initial stages of product or service development (start-ups) is even less frequent, with only a handful of sources available.

There are several Funds devoted to the area of digital innovation, ICT for development and technology innovation. However, most of them tend to support the creation of ICT infrastructure or the establishment of conditions that would facilitate access to ICT, rather than the development of ICT applications for a specific development sector—for example, agriculture. In general, Funds are vague as to the nature of the “innovation” activities they would support, which leaves the proponent to decide whether their proposal would fall or not within the realm of interest of each Fund. Size of the grants tend to be small (less than US\$50,000 each); project duration tends to be short—12 months seems to be the most common duration—which may limit the long-term sustainability of the efforts they support. While there is some coalition among funding sources at the regional level (Latin America and Caribbean, Africa and Asia), funding seems to be too dispersed to be able to have significant impact to solve the problems of poverty and hunger in those regions. Finally, there are several Funds devoted to supporting ICT and Digital Innovation in their own countries, including some in the developing world; multi-country Funds are less common.

Principal lessons learned from experience by other donors in the field of financing innovation sources—specifically ICT for Development funding—point at: (i) the importance of local ownership for sustainability and, concomitantly, the need to invest in capacity-building; (ii) the relevance of government (local, national and international) participation to provide conditions that make innovation viable—clear regulations, competitive environment, protection of intellectual property, among others; (iii) the role of private sector involvement, particularly for scaling up and devising commercial applications; and (iv) the need to invest in social inclusion for the projects to achieve tangible social impact.

Observations from success and failure stories from other donors as well as lessons learned in the implementation of innovation funding in developing countries have both been used to shape the current proposal. The specific nature and workings of the proposed financial instruments will need to be discussed in detail and defined further.

A PROPOSED FAO DIGITAL STRATEGY AND INNOVATION FUND FOR AGRICULTURE DEVELOPMENT

The authors present a scenario for the establishment of a funding mechanism to support the implementation of a Digital Innovation Program under FAO’s Digital Strategy, by way of a Multi-Donor Digital Innovation Trust Fund (MDIF) whose objective would be to promote flagship digital innovation solutions to improve decision-making and/or enhance productivity of end-users (farmers, fishers, forest dwellers among others) in the field, at the same time generating society-relevant public goods. The Trust Fund would prioritize those project proposals that show economic viability, a vital attribute to ensure replicability and sustainability of digital innovation products and services that would be generated by those projects once funded.

Projects supported by the Trust Fund would contribute directly to the attainment of FAO's strategic objectives. The alignment of the Trust Fund's objectives and goals to those of FAO would be described in the Trust Fund's Results Framework.

Specifically, the MDIF would finance:

- a. Development of new digital-innovation-based business models and processes
- b. Development of digital innovation ecosystems in agriculture
- c. Start-up projects to help beneficiaries test their strategic choices and/or lay the ground for further work and investment in the future; and
- d. Training and knowledge transfer among beneficiaries and between beneficiaries and knowledge providers worldwide.

The risk of funding initiatives that may not live up to their potential in terms of scalability or sustainability would be mitigated through the accumulated experience of the Trust Fund's future partners, who would have developed significant knowledge on existing markets and opportunities to help the Trust Fund choose those projects that have the greatest potential of success. Partnering with other sources of funding would also be crucial in securing resources additional to those contributed by the Trust Fund, to support projects beyond the start-up phase.

Beneficiaries would be able to apply to any one of these lines of financing and could re-apply to a different line of financing if the results of the first financing are promising. For example, a beneficiary could be awarded funding to improve its business model, and after concluding adaptations, apply to be financed as a start-up. To support beneficiaries in all these areas, the Trust Fund would provide GRANTS to cover the following three kinds of activities: (i) technical cooperation, to provide specialized consulting services to help beneficiaries in developing new business models and processes, buttress their implementation and train their staff in specific areas related to the project; (ii) pre-investment, to allow beneficiaries to apply or contract proper feasibility analysis, conduct market research and build solid business plans for their project concepts; and (iii) investment, to provide seed funding to start-up project proposals that have proven they can be beneficial and sustainable.

The proposed MDIF would involve the private sector, other UN agencies and multinational and multi and bi lateral development agencies in this effort to multiply the impact of this initiative, take full advantage of creativity developed elsewhere, and reduce the potential of duplication among development agencies active in this field.

The Trust Fund would receive applications from FAO beneficiary member countries' end-user associations (such as farmer cooperatives or unions); incubators, innovation accelerators, impact hubs; non-for-profit non-governmental organizations that support those sectors; and small and medium sized local enterprises involved in those sectors. Local government agencies responsible for the same areas could participate in the projects providing partial financing or in-kind contributions.

In replicating and disseminating MDIF best practices among FAO's 2,000+ currently active projects in FAO's five regions (Africa; Asia and the Pacific; Europe and Central Asia; Latin America and the Caribbean; and Near East and North Africa), indirect beneficiaries of the MDIF could potentially be the entire population served by FAO.

The Trust Fund would accept proposals that present innovative, scalable and sustainable solutions in the following areas:

- a. Develop local, regional or international markets for digital innovation-based innovations, to match supply and demand for digital innovation products and services –a gap between supply and demand is a widespread problem that affects potential beneficiaries in most developing countries. Examples of this type of projects could be:
 - Proposals to develop supply-and-demand networks for innovation products and services, matching an existing or newly developed product or service (the supply) with a user who could benefit from acquiring them (the demand).
 - Project-specific market research for digital innovation products and services (ICT, digital innovation products and services generated through R&D) to identify opportunities for their sale and distribution, using readily available research on regional and global markets.
 - Support to establish user organizations (cooperatives, etc.) allowing them to reach critical mass to become attractive to markets while at the same time allowing potential providers to achieve economies of scale and therefore reduce price of digital innovation products and services offered.
- b. Improve beneficiary organization's business models and internal processes through the introduction of digital innovation products and services to increase efficiency and improve production. Examples of these types of projects could be:
 - Conduct analyses to identify existing deficiencies or inefficiencies in beneficiaries' business models or processes and identify digital innovation-based solutions to overcome them
 - Identify new opportunities to increase their participation in the value chain of their products using digital innovation in any phase of product/service development
- c. Generate new digital innovation products and services with a clear promise to have social and economic viability to solve clearly defined problems along the whole value chain of target agricultural, livestock, forestry or fishery products. Examples of this type of projects could be:
 - Design new digital innovation-based products and services that could be marketable including adequate pre-investment resources
 - Develop prototypes of new digital innovation products with specific applications to solve also specific problems identified
 - Develop detailed proposals for the provision of digital innovation-based services that would solve a specific problem or add to the socio-economic viability of a given product
- d. Develop or improve digital ecosystem structures and support their operation; for example, establishment of innovation labs, with associated incubators, accelerators and hubs, and their respective connections to the local, regional or international Trust Fund structure

The Trust Fund would receive both, earmarked and general contributions. When individual donors or associations of donors require earmarking of their contributions, the Trust Fund would open a separate "account" to accommodate donor priorities --specific regions and/or purposes. This option would give the Trust Fund versatility and increase its appeal to different donors by offering diversity of opportunities.

General contributions would be un-tied funds provided by donors for the specific purpose of financing project proposals presented to the MDIF, trusted to FAO in management. Such general contributions would be subject to matching by Ordinary Capital (OC) contributions by FAO and thus reported to donors along with the appropriate financial information.

FAO will collect and disseminate best-practices generated by field projects supported by MDIF to multiply the reach of its accomplishments within FAO's and UN's online platforms to support Sustainable Development Goals progress. FAO will also include information on innovative products, services,

models and processes offered by other sources, further contributing to project beneficiaries' decision-making in the structuring and running of their respective projects.

Potential partners —particularly private companies— may be unwilling to transfer funds for FAO to manage. To facilitate such partnerships, and under FAO's new delivery arrangements which allow FAO to delegate project delivery to an implementing agency, one such third party would be hired—a non-for-profit non-governmental agency—to coordinate implementation. This arrangement would streamline management and facilitate oversight.

To prepare the initial steps in the implementation of the Trust Fund, as well as to allow for fine-tuning of its internal regulations, a first-year batch of projects would be developed in coordination with identified partners. Such first group would be presented as a sample and processed as a single operation under FAO's project cycle. This preparatory phase would further allow to work closely with FAO's business units engaged in implementing other project funding instruments to maximize synergies and minimize duplication or overlap.

Socio-economic benefits from each funded project can be expected to derive from: (i) enhanced economic viability and sustainability of each beneficiary enterprise and endeavor resulting from the insertion of more advanced and appropriate technology innovation solutions; (ii) greater reach—in terms of number of beneficiaries and geographic scope of such benefits—derived from the utilization of digital innovation solutions that typically multiply access to the same products and services offered through traditional means; (iii) enhanced opportunities afforded to specific groups such as women, youth, persons with disabilities, for whom digital innovation products and services have been proved to facilitate access provided adequate and specific support is present; (iv) greater awareness of the potential benefits that can be accrued by digital innovation-based investment among local societies and governments, with the potential of a multiplying and replicating effect.

FUTURE RESEARCH DIRECTION

Further analysis is needed to identify those which could hold the greatest potential to become valuable partners to the proposed Trust Funds. Exploratory interviews with each should follow, prioritizing those which already have some sort of agreement established with the IADB and the FAO. After canvassing the field, we should be working on a gap analysis to identify possible niches that could be occupied by the IADB and the FAO, as well as to better define the nature and scope of the Funds. The latter activity would involve marketing work through the development of the Fund's unique "value proposition" (a "resonating focus" approach). Once the outlines of the proposed Funds have been decided, partner-specific proposals of collaboration would need to be produced and discussed.

CONCLUSION

There are several Funds devoted to the area of digital innovation, ICT for development and technology innovation. However, most of them tend to support the creation of ICT infrastructure or the establishment of conditions that would facilitate access to ICT, rather than the development of ICT applications for a specific development sector—for example, agriculture. In general, funds are vague as to the nature of the "innovation" activities they would support, which leaves the proponent to decide whether their proposal would fall or not within the realm of interest of each fund. Size of the grants tend to be small

(less than US\$50,000 each); project duration tends to be short—12 months seems to be the most common duration—which may limit the long-term sustainability of the efforts they support. While there is some coalition among funding sources at the regional level (Latin America and Caribbean, Africa and Asia), funding seems to be too dispersed to be able to have significant impact to solve the problems of poverty and hunger in those regions. Finally, there are several Funds devoted to supporting ICT and Digital Innovation in their own countries, including some in the developing world; multi-country Funds are less common. Principal lessons learned from experience by other donors in the field of financing innovation sources—specifically ICT for Development funding—point at: (i) the importance of local ownership for sustainability and, concomitantly, the need to invest in capacity-building; (ii) the relevance of government (local, national and international) participation to provide conditions that make innovation viable—clear regulations, competitive environment, protection of intellectual property, among others; (iii) the role of private sector involvement, particularly for scaling up and devising commercial applications; and (iv) the need to invest in social inclusion for the projects to achieve tangible social impact.

The two scenarios presented for the Inter-American Development Bank (IADB) and the Food and Agriculture Organization of the United Nations (FAO), would comply with the above conditions.

KEY TERMS AND DEFINITIONS

Digital Innovation (DI): The DI is the application of new technologies to existing problems or practices. The process is ongoing, but it can be better understood as taking place in waves, with each way propelled by advancements in technology.

Knowledge Economy (KE): The KE is an interconnected, globalized economy where knowledge resources such as know-how, expertise and intellectual property are as critical as other economic resources such as land, natural resources, or even manpower. Under this concept, Knowledge is recognized as a source of competitiveness, where value lies in innovative ideas, services, and networks, using technology as an instrument, not as an end.

Sustainable Development Goals (SDGs): The SDGs are the blueprint to achieve a better and more sustainable future for all. They address the global challenges we face, including those related to poverty, inequality, climate, environmental degradation, prosperity, peace, and justice. The SDGs are interconnected, and the challenge is to achieve them by 2030. Technology plays an important role in achieving the SDGs.

Auction-Based Pricing in Cloud Environment

Branka Mikavica

Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia

Aleksandra Kostic-Ljubisavljevic

Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia

INTRODUCTION

The rapid development of technologies triggered the emergence of cloud computing. Cloud computing enables network access to a scalable and elastic pool of shareable physical or virtual resources. Resources in the cloud environment are generally provisioned as cloud instances, i.e. Virtual Machines (VMs) with the required CPU, memory and I/O resources. The main advantages of cloud computing are scalability, low costs, dependability, service-driven, self-healing and multi-faceted. However, there are also numerous challenges including a vulnerability, bandwidth costs, transparency access, trust, reliability, security, availability, resource management, task scheduling, and performance (Gullhav & Nygreen, 2016; Sebastio, Gnecco & Bemporad, 2017). The dominant factor in supporting customers to use virtual resources and move towards cloud computing is pricing. Cloud customers pay for required cloud resources depending on instance type and pricing mechanism applied. In addition, different levels of guarantees in terms of availability and termination are possible. Pricing mechanisms in the cloud environment can be generally classified into static and dynamic. The static pricing mechanisms are the dominant scheme in the cloud environment and involve the charging the fixed price per hour and per instance. The dynamic pricing mechanisms include charging the usage of cloud resources as long as the cloud customers' bids are equal or exceed the price per instance and per time interval, determined by the cloud provider (Alzhouri & Agarwal, 2015). For example, Amazon Elastic Compute Cloud (EC2) uses three different pricing options for cloud resources: Reserved instances, On-demand instances, and Spot instances. Reserved instances are provided with long-term availability guarantees, On-demand instances are provided for specific time periods and are guaranteed to be available once assigned, and Spot instances are provided through an auction-like mechanism, but their availability depends on the time-varying Spot price. Reservation and On-demand pricing mechanisms are considered as static since prices for cloud resources are invariant for both under-utilization and over-utilization of the resources. Idle cloud resources can be offered as Spot instances. This purchasing option offers no guarantees on minimum sustained availability. Submitting a bid for the access to Spot instances, cloud customers specify the maximum price they are willing to pay. The actual price they pay is not the value of the bid, but the value of the Spot price. Cloud provider set Spot price depending on the availability of the idle resources and current demand. When the Spot price exceeds the value of the bid, the Spot instance is terminated. Cloud provider can also revoke Spot Instances when the supply of available Spot Instances decreases. Recently, a new variety of Spot instances, Spot Block instances, are introduced. These instances run continuously for a finite duration, up to 6 hours. When cloud customer submits a bid, two parameters need to be specified: the value of the bid (the maximum price willing to pay per hour) and the Block

DOI: 10.4018/978-1-7998-3473-1.ch008

duration parameter (the number of hours that Spot Block instance will run). The Spot Block instance is terminated only at the end of the Spot Block duration.

As a dynamic form of pricing, auction mechanisms can be an effective and promising solution for profit maximization of cloud providers. These mechanisms provide price variation depending on the changes in supply and demand by creating competition among cloud customers. Therefore, auctions can balance supply and demand for cloud resources. They support cloud customers for truthful bidding and allocate the resources to the customers that value them the most. Various auction-based allocation and pricing mechanisms can be used for cloud resources: Uniform price auctions, Second-price auctions, Combinatorial auctions, Double auctions etc. In this chapter, the analysis of different auction-based mechanisms for pricing and allocation of cloud resources is provided.

BACKGROUND

Auction mechanism is also referred as market-clearing mechanism that equates demand and supply. It is a widely adopted mechanism for resource allocation in telecommunications. For instance, auctions are used for efficient and effective spectrum allocation in mobile communication, and to trade-off electricity using spot marketing. There are three entities in an auction: seller, buyer and auctioneer (Baranwal, Kumar, Raza & Vidyarthi, 2018). Seller owns the commodities, offers them to the buyers and earns profit. In terms of cloud computing, cloud providers are sellers, while commodities are cloud resources (for instance, various types of VMs). Buyers are cloud customers who purchase the commodities, i.e. cloud resources from the cloud providers. Auctioneer is the entity that performs an auction. It is an intermediate agent that acts as the market maker. Since the auctioneer stores the repository of the historical transactions, it provides support for cloud providers to identify the new trends in cloud resource allocation. Auctions consist of two sub-processes: winner determination and payment mechanism. These processes are performed in six steps, as shown in Figure 1.

The auction starts with the collection of bids from various bidders by the auctioneer. Set of rules and constraints in an auction need to be specified clearly. Constraints might be bid expiry, resource availability, bidder's budget, time period for resource provisioning, etc. Bids that do not satisfy the given set of constraints are canceled in validation phase by the auctioneer. Step 2 refers to the auction closing. Auctioneer can close the auction and finish accepting the bids upon certain conditions (sufficient number of bids received, time limit specified for bidding, availability of resources, etc.). Once the auction is closed, any change in a bid or accepting new bids is not allowed. The value of each bid is computed after closing the auction (Step 3). Bids are then sorted, depending on their values. In Step 4, resources are ranked according to their intrinsic value. Depending on the predefined rules, some bidders are selected as winners in resource allocation (Step 5). Computational complexity of the winner determination increases with the increase in the number of the participants in the market. In Step 6, cloud customer pays according to the defined pricing mechanism. If the pricing mechanism is properly implemented, the auction is truthful, i.e. incentive compatible.

Various auction-based pricing and allocation mechanisms in the cloud environment are proposed (Kumar, Baranwal, Raza & Vidyarthi, 2017; Kumar, Baranwal, Raza & Vidyarthi, 2018; Lu, Yu, Zhu, Li, 2018). The current research on auction-based pricing mechanisms in the cloud environment is primarily focused on a static, single type resource with a single requirement. The issue closely related to pricing is cloud resources allocation. A comprehensive literature review of auction mechanisms for cloud resource allocation is provided by Sheikholeslami and Navimipour (2018). There are many possible classifications

Figure 1.

of the auction mechanisms in cloud environment (Baranwal, Kumar, Raza & Vidyarthi, 2018). In this chapter, the research focus is on the one-sided, double-sided, and combinatorial auction mechanisms.

In one-sided auctions, bidders submit their bids without awareness of other bids. The highest bidder wins an auction. A well-known auction mechanism is Vickrey auction, also referred as Second-price auction. The resources are allocated to the second highest bidder. A widespread used auction-based method in the cloud environment is Uniform price auction (Zhang, Gurses & Boutaba, 2011). In such an auction mechanism, the provider allocates resources to bidders in decreasing order of their bids, while the selling price equals the lowest winning bid. The concept of the marginal bid, i.e. the highest unsuccessful bid for pricing and allocation of cloud resources under Second-price auction is proposed by Lin, Lin & Wei (2010). The proposed concept achieves high revenue for the cloud provider, with low response time. However, it provides low revenues for the customers.

In double-sided auctions, both the cloud providers and cloud customers place their bids. If cloud providers' offers and cloud customers' bids can be placed at any time, the auction is referred to as Continuous Double Auction. A detailed study of double auction-based mechanisms application in a cloud environment along with a framework for a future cloud market using double auction is provided by Kumar, Baranwal, Raza & Vidyarthi (2017). In the two-sided market, a cloud customer can purchase cloud resources from multiple providers, while a cloud provider can rent its resources to multiple customers. Different cloud providers offer different pricing mechanisms. Hence, it is often very difficult for cloud customers to make an optimum request. However, the double auction can be an effective pricing and allocation mechanism for two-sided markets.

Combinatorial auctions are often used for pricing and allocation of cloud resources. In the combinatorial auction, a cloud provider offers a group of resources, in form of bundles, while cloud customers

submit their bids. Therefore, there are more than two resource types in the auction. Combinatorial auctions are considered as a convenient and efficient mechanism for both cloud providers and customers. The problem of allocation VM instances of several types to several customers requesting a set of VM instances of different types is analyzed by Zaman & Grosu (2013). They proposed two combinatorial auction-based allocation mechanisms. The first mechanism considers the situation with few types of items and many instances of each type. The other mechanism determines allocation based on the customers' bids and the total number of items they demand, with consideration of the relative sizes of VM instances. These two mechanisms are further compared with the fixed-price based allocation mechanisms. It is shown that combinatorial auction-based mechanisms outperform the fixed-priced mechanisms in terms of resource utilization, revenues and allocation efficiency (Zaman & Grosu, 2013). These mechanisms provide high revenues for cloud providers, high resource utilization with low costs. However, cloud customers' benefits are not considered.

BENEFITS OF AUCTION-BASED PRICING MECHANISMS

Despite their simplicity, static pricing mechanisms do not support revenue maximization since idle resources earn no revenue and even introduce additional costs due to depreciation. In addition, demand for cloud resources varies over time. Therefore, the use of dynamic forms of pricing mechanisms is appropriate to optimize the cloud provider's revenue. Price adjustment based on actual or forecasted dependences between supply and demand can enable demand shifting from the periods of high traffic load to the periods of low traffic load. The aim of dynamic pricing mechanisms is to charge the idle resources at a low price to improve resource utilization and raise the price if the demand for cloud resources increases (Wan, Zhang, Gui & Xu, 2016). Cloud providers offer a variety of computing and storage resources to different types of customers by different pricing mechanisms. Therefore, a convenient pricing mechanism from cloud customers' perspective enables efficient service provisioning at least price. On the other hand, an effective pricing mechanism from the cloud providers' perspective provides profit maximization with increased resource utilization. Different auction mechanisms are convenient to use as a form of dynamic pricing in a cloud environment due to several advantages (Toosi, Vanmechelen, Khodadadi & Buyya, 2016). Auctions encourage cloud customers to reveal the true values they are willing to pay for required resources, ensure that resources are allocated to customers that value them the most (Zaman & Grosu, 2013), and the prices are corrected depending on demand and supply conditions by creating competition among customers. The efficiency of cloud resource usage is improved under auction-based pricing and allocation mechanisms (Taifi, Shi & Khreishah, 2011). Thus, such pricing mechanism can effectively determine the market value of cloud resources, especially when allocating relatively limited resources to a potentially large number of cloud customers (Chichin, Vo & Kowalczyk, 2014).

From cloud customers' perspective, auction-based pricing mechanisms set, on average, lower prices than fixed pricing mechanisms (Jung, Chin, Chung, Yu & Gil, 2011; Kaminski & Szufel, 2015). Amazon EC2 Spot pricing, as a typical example of auction-based pricing, enables significant savings if On-demand instances are being replaced by Spot instances (Javadi, Thulasiram & Buyya, 2013). Some empirical studies show that with the proper bids, savings over On-demand instances can be up to 36% (Leslie, Lee, Lu & Zomaya, 2013). In addition, Spot pricing improves customers' satisfaction (Xu & Li, 2013). In situations when the demand for On-demand and Reservation instances is high, customers can shorten waiting time by using the alternative instances, Spot instances or their variety - Spot Blocks. Additionally, combinatorial auctions enable more convenient trading of different types of cloud resources for the

customers with high requirements. With the appropriate market structure, it is possible to achieve fair interactions between cloud providers and cloud customers through an auction pricing mechanisms. Thus, higher social welfare is enabled for the entire cloud environment (Shi, Zhang, Wu, Li, & Lau, 2016).

The recently introduced form of cloud idle resources, Spot Block instances, provide several advantages over Spot instances. Cloud customers can choose Spot Block duration without termination (1-6 hours) in an auction-based allocation scheme. Therefore, the utilization of a cloud provider's resources is improved since cloud customers can use cloud idle resources for the less flexible tasks. Once determined, the Spot Block price is fixed for a predefined time period, which also improves cloud customers' satisfaction in cloud service provisioning. If an auction mechanism is appropriately set, Spot Block instances are a cost-efficient solution for workloads that require uninterrupted provisioning in duration up to 6 hours. The generalized Second-price auction can be convenient for Spot Blocks allocation from the cloud provider's perspective since it assures greater revenues. However, Uniform price auction provides greater savings for cloud customers (Mikavica & Kostic-Ljubisavljevic, 2018).

BIDDING STRATEGIES IN AUCTION BASED PRICING MECHANISMS

In auction-based mechanisms for pricing and allocation of cloud resources, selection of appropriate bidding strategy is crucial from cloud customers' perspective. The cloud provider allocates its idle resources to the cloud customers based on all received bids and on the available resources through an auction-based mechanism. Once bids are submitted, the cloud provider aggregates bids and demands and reconcile them with the supply. The usage of idle resources provides significant cost advantages for both providers and customers. However, customers need to make the decision regarding the bidding strategy. In general, the chosen bidding strategy impacts the following performance metrics: costs, wait time and interruption rate (Karunakaran & Sundarraj 2014). Lower bids can assure lower costs. However, the other performance metrics such as task completion time and interruptions are deteriorated. Therefore, cloud providers often recommend bidding high in order to increase the possibility of uninterrupted cloud instance running. Price-sensitive cloud customers usually submit low bids. This means that they are willing to pay only a low price for cloud VMs. However, VMs with a low bid might have a low availability and high possibility of being revoked if the market price increases more than the bid price. Frequent revocations can lead to application downtimes, prolonged deadlines and decreased performances. Therefore, bidding presents cloud customers' tradeoffs between costs and availability/revocation-rate. Appropriate bidding strategy should minimize costs with different constraints including deadlines, for a wide range of applications. The complexity of bidding is the reason why, despite lower prices, auction-based renting of cloud resources has a low usage (Sharma, Irwin & Shenov, 2017).

Several bidding strategies are analyzed by (Sharma, Irwin & Shenov, 2017): bidding close to the reserved instance price, bidding above the average Spot price, bidding close to the On-demand price and bidding above the On-demand price. Their study shows that bidders who choose the strategy of bidding close to the reserved instance price reduce costs on the expense of greater waiting times and higher interruption rate. Furthermore, bidders adopting bidding above the On-demand price achieve the lowest waiting times and interruption rates but higher costs, in comparison with the other bidding strategies. In addition, it appears that marginal increase in cost is much higher than the marginal decrease in waiting times and interruption rates. However, 35% of bidders chose to bid above the On-demand price. Bidding above the average Spot price and bidding close to the On-demand price ensure a satisfying tradeoff between costs, waiting times and interruptions, while bidding close to the On-demand price

provide the maximum marginal difference. Therefore, the strategy to bid close to the reserved instance price is convenient for price-sensitive cloud customers with flexible tasks' deadlines. The strategies for bidding above the average Spot price and bidding close to the On-demand price are acceptable for cloud customers with equal requirements in terms of costs, waiting times and interruption rates.

Pricing and different bidding strategies (bidding close to the Spot Block price for one hour in previous time interval, bidding close to the Spot Block price for six hours in previous time interval, and bidding close to the On-demand price) for Spot Block instances along with the cloud provider's revenue analysis are proposed by Mikavica & Kostic-Ljubisavljevic (2018). Bidding and allocation of Spot Block instances are more complex as compared to regular Spot instances. Additional complexity is introduced by allowing that Spot Block instance runs without termination even if the market price exceeds the Spot Block price. Since Spot Block prices per hour are different for different Spot Block Duration, bids cannot be sorted only based on their value. A model for the translation of bids into unit bids in order to enable their easy comparison in an auction mechanism is proposed by (Mikavica & Kostic-Ljubisavljevic, 2018).

The optimization of cost-availability tradeoff can be achieved through different bidding strategies. When a cloud customer increases their bid, their availability also increases at the expense of more pay per hour. Furthermore, the availability of idle resources is not sensitive to bidding for a large range of bid prices. Similarly applies to the costs, since there is no penalty for bidding high due to the auction's properties. Another important metric is the frequency of revocations. Regardless of the bid price, revocations are inevitable when using cloud idle resources. In accordance with, some studies show that cloud customers need not employ some complex bidding strategies (Sharma, Irwin & Shenov, 2017). Instead, customers should choose appropriate instance type in order to reduce the revocation risk and bid price equal to the On-demand price. However, the recommendation is to select different instance types and to apply migration to other instance types if necessary. This can significantly reduce the impact of revocations and concurrently to decrease costs. The effectiveness of cloud resources can also be improved. Therefore, the combination of proper selection of instance types and fault tolerance policies are key factors that determine performance and costs.

SOLUTIONS AND RECOMMENDATIONS

The optimization problem of the cloud provider's revenue maximization or resource allocation is NP-hard or NP-complete (Song, Yao & Golubchik, 2013; Wang, Ren & Meng, 2012). The implementation of such pricing and allocation mechanism requires a lot of effort and managerial overheads (Xu & Li, 2013). In addition, untruthful bidding and mutual cooperation between cloud customers can cause that auction-based pricing mechanism to become unprofitable for cloud providers (Karunakaran & Sundarraj, 2013). Cloud customers should recognize and control potential anchors that can influence their bid decision making. These anchors can be provider's recommendations, customers' guidelines, spot-price history, peer bids etc. In order to achieve an effective auction mechanism, customers should ensure that their bid decisions closely reflect their costs, waiting time and interruption rate tradeoffs. Some studies show that bidding above On-demand price is not efficient (Karunakaran & Sundarraj 2014). Therefore, cloud customers should choose appropriate bidding strategy with great caution.

One of the most important requests that auction should satisfy is truthfulness. An auction is truthful if participants in the auction cannot increase their revenues through untruthful behavior. Such truthful auction-based pricing and resource allocation mechanism is possible only if perfect knowledge about bidders' valuations is available (Wang, Li & Liang, 2012). Designing a mechanism that benefits both

cloud customers and cloud providers is of high importance. Cloud resource pricing and allocation with multiple customers' requests can be performed by a truthful auction-based mechanism, such that both cloud providers and cloud customers can benefit (Xie, Zhang & Zhang, 2017). In practice, cloud customers rarely know the exact capacity needed for completion of their tasks. Therefore, customer's task requirements are often inconsistent with providers' resource (Lu, Yu, Zhu & Li, 2018). A truthful double auction mechanism can be efficient in solving that issue.

Cloud customers are also exposed to some limitations in the auction-based provisioning of idle resources. The main limitation relates to the availability/reliability of cloud instances. Cloud provider controls termination of idle resources depending on the demand-supply relations and applies price adjustment. Thus, cloud instances can be terminated at any time. Performances are uncertain, which negatively impacts on the economic advantages of using cloud idle resources. Moreover, the potential frequent instance termination could eventually be inefficient compared to static pricing mechanisms (Shi, Zhang, Wu, Li & Lau, 2016). Therefore, dynamic pricing mechanisms are considered unsuitable for workloads with little flexibility and long-running tasks (Xu & Li, 2013). Another important issue in terms of auction-based pricing mechanisms is appropriate bidding. Bidding low prices can result in extremely low execution time without significant cost savings while bidding high prices can lead to large cost increase without reduction computation time (Kaminski & Szufel, 2015).

Most of the proposed pricing and allocation auction-based pricing mechanisms consider uni-attribute where cloud customers bid on price only. Parameters, such as reputation, customers' experience, etc. should also be taken into consideration (Baranwal & Vidyarthi, 2015). Therefore, a multi-attribute auction is a convenient solution that allows cloud customers to bid on various attributes of resources along with the price. The cloud provider chooses a winner based on the defined multi-attributes. In addition, cloud providers offer a collection of resources in form of bundles. Bundling based on the cloud customers' interests with maximization of cloud providers' profits is a huge research challenge. Combinatorial auctions seem like a promising solution since customers can bid for a bundle of dependent and complementary resources. Moreover, when there are multiple cloud providers and multiple cloud customers, it is preferable to apply double auctions, due to their greater efficiency compared to several single sided auctions. Cloud resources pricing and allocation occur either when the customers' request appears, or cloud resources become available. Each cloud customer has a practical budget limitation for a certain time period. Therefore, online auction mechanisms are appropriate due to time dimension consideration.

FUTURE RESEARCH DIRECTIONS

The coordination between cloud providers in an auction-based resource provisioning in the cloud market is an important issue. Hence, it would be beneficial to introduce the game theory into the auction mechanism, and potentially, to adopt auction-based resource allocation mechanisms between different cloud providers. Most of the game-theoretic studies on pricing and allocation of cloud resources consider only the competition between cloud customers competing for the resources of a single cloud provider (Valerio, Cardellini & Presti, 2013; Ma & Huang, 2012; Sowmya & Sundarraj, 2012). Truthfulness in an auction for cloud resources pricing and allocation is very complex and requires further analysis. Moreover, the tradeoff between efficiency and truthfulness should be also considered. Achieving a fair, truthful, efficient and revenue-maximizing auction mechanism is a highly challenging issue and requires a comprehensive analysis in the future.

Cloud resources' allocation and pricing should be considered from both the economic and computational points of view. From economic point of view, individual rationality should be further analyzed. The computational perspective focuses on the complexity of given auction mechanism. The development of a simple auction mechanism that can be executed in a reasonable amount of time is complex. In addition, all participants in an auction should communicate with each other with the least complexity. Furthermore, resource allocation and pricing in specific cloud service models should be analyzed. These challenging issues are potential topics for future research.

Double-sided auctions are computationally and economically efficient when there are very large number of participants in the market. Although practical implementation of double-sided auctions in cloud environment is not performed yet, there is great potential of its implementation. Since cloud resources are provided to the customers by the multiple providers, to design a standard for the resource offering is a complex task. The development of such design could be one of the future research directions. Additionally, the effects of migration of cloud customers from one to another cloud provider and associated costs should also be considered.

Further research direction could be to design game-theoretic strategies with multiple providers competing with each other. Cloud customers choose different strategies to increase their workflow completion time while cloud providers adjust their prices based on the market price in competition with each other. Therefore, the analysis of the market behavior of participants in the auction is another issue that should be improved. Optimizing costs, power consumption, the under-utilization of resources, requests' loss and balance load are challenging issues. Introduction of Service Level Agreement (SLA) management based resource allocation can improve the overall performance and hence, it should be the segment of future research. Cloud customers' bidding strategy depends on numerous factors including characteristics of their workload, deadline constraints, number of the cloud providers, alternative SLAs, etc. There are several issues related to bidding that might be improved, including bidding strategies in the presence of the irrational bidders and relations between price predictions and chosen bidding strategies.

CONCLUSION

Auction-based pricing and allocation of cloud resources receive a great attention among the researchers. Dynamic pricing has numerous advantages that influenced leading cloud providers to start offering their resources through different dynamic pricing and allocation mechanisms. Auctions are a very convenient solution for cloud providers' revenue maximization. Along with, they can provide incentives for cloud customers for truthful bidding. Pricing, bidding, and allocation of cloud resources require a comprehensive, multidisciplinary approach. These issues can be analyzed from different perspectives including price modeling, price prediction, bidding strategies, methods to improve the availability of resources, variants of fault tolerance etc. In this chapter, the major benefits of auction-based pricing and allocation mechanisms for cloud resources are emphasized. The importance of the selection an appropriate bidding strategy is also analyzed. Despite their advantages, auction-based mechanisms raise some research challenges. This chapter provides an insight into open issues and suggests possible solutions.

KEY TERMS AND DEFINITIONS

Auction Mechanism: Often used pricing mechanism for cloud provider's idle resources. If properly set, an auction mechanism should support customers to bid truthfully for cloud resources and allocate resources to customers that value them the most.

Cloud Customer: Content/service provider or end user that rents cloud resources for execution specific tasks depending on their requirements.

Cloud Provider: Undertaking that provides storage and computational resources to cloud customers depending on appropriate pricing and allocation mechanism and resources' availability.

Cloud Resources: Virtual machines (VM) with specific computational and storage capacities provided to the cloud customers in the form of cloud instances. Cloud customers can rent those instances depending on their availability and applied pricing mechanism.

Pricing and Allocation Mechanism: Mechanism that determines which cloud resources will be allocated to which cloud customers at a specific price and specific duration.

Spot Block Instances: Subset of cloud provider's Spot instances. Cloud customers submit bids, determining the maximum price they are willing to pay for specific cloud instance per hour and the Spot Block duration up to six hours. The Spot Block runs uninterrupted up to Spot Block durations expires, regardless on the Spot Block prices.

Spot Instances: Cloud provider's idle resources provided through an auction-like mechanism, where cloud customers submit bids, i.e. maximum price they are willing to pay for specific cloud instance of one-hour duration. The spot instance can be terminated whenever the submitted bid exceeds the Spot price determined by the cloud provider.

Taking a Peek Behind the Corporate Finance in China

INTRODUCTION

One of the most widely used concepts in corporate finance is the financial structure (Ayturk, 2017; Kowalewski, Stetsyuk & Talavera, 2007). Certain authors (Chi & Young, 2007; Taylor, 2013; Shi & Zhang, 2018), in their specialized publications, consider the terms financial structure, capital structure and capitals' structure to be synonymous. The financial structure takes into account the component of all company capitals and it may be rendered as ratio of own capitals to company debts, as ratio of company's internal to external financing sources, or as ratio of short-term financing to long-term financing (Elston, Chen & Weidinger, 2016).

Howsoever, an enterprise has the possibility to choose from several alternative financial structures (Wan & Yuce, 2007). In addition to the general term of capital structure, there is the term of optimum capital structure represented by the ratio of own capital to borrowed capital which leads to maximizing the shares' market price and which determines a minimization of average weighted cost of the enterprise's capitals.

In this context, a rather controversial issue in corporate finance related to capital structure was presented by Modigliani and Miller in a remarkable specialized work published in 1958. Subsequently, other theories were developed, which had as starting point the theoretical framework set by the two authors. Modigliani and Miller (1958) in their studies related to the manner of selecting enterprise financing, reach a paradoxical conclusion in the sense that various types of financing may be equivalent and then there cannot be an optimum financial structure in order to be able to optimize the capital cost. They explain that the capital cost remains relatively constant in situations in which the company adopts an indebtedness policy benefitting from a low interest because, in such situation, the cost of own capitals may increase due to the existence of risks, associated with the new loans (the shareholders' claims increase). Overall, the average weighted cost will be approximately the same. Moreover, the cost of capitals in the form of dividends cannot be compared to the cost of the other sources of financing.

In the classic western corporate finance theory, investors hold the right to vote in the market. When the incumbent management of the company is inefficient in operation, the original shareholders or the new shareholders acquiring company will acquire sufficient shares to obtain the control of the company and create a new receiver. Although U.S. laws have more legal restrictions on the takeover of compa-

DOI: 10.4018/978-1-7998-3473-1.ch009

nies in recent years, the takeover market of the company remains largely effective in terms of external regulatory functions.

Although considering the information asymmetry and incomplete contract factors in the western classic corporate finance theory, it is considered that given the information premise, investors are completely rational and the market is effective (Koksal & Orman, 2015).

In China, due to the short development time of capital market, the phenomenon of speculation and stock price manipulation are more and the protection to investors is also weaker. Therefore, investors cannot correctly identify the signal of enterprise quality according to the relevant financial information (Wintoki, Linck & Netter, 2012).

Most of the listed companies, because of the phenomenon of “single domination”, when the incumbent management of the company is not efficient, unless the major shareholder is willing to negotiate the transfer of non-negotiable shares through the OTC, the outsiders are difficult to buy enough outstanding shares to achieve the purpose of taking over the company, that is, the imperfection of the company’s control market is difficult to play the role of external governance (Liu, 2017).

At the same time, Corporate Social Responsibility (CSR) is a useful instrument centered around two main directions: (1) increasing the competitiveness of Romanian companies based on China or foreign capital on the market; and (2) improving the responsibility of local communities, multinational companies, large companies, and SMEs regardless of their capital, whether public or private. The results of empirical studies on CSR communication have indicated that corporations in China are moving more easily from “visible” involvement to “real” involvement, proving a certain degree of progress and maturity when compared to the situation encountered before the economic and financial crisis in 2007. However, there is still a set of challenges such as the difficulty of quantifying the precise budgets allocated to CSR initiatives thus far by companies belonging to international or multinational groups and the inadequate frequency of communication channels selected by companies in transmitting their CSR messages (Morck & Yeung, 2014; Shi & Zhang, 2018; Chen, Li & Xin, 2017).

Later on, Ross, Westerfield & Jaffe (1993) emphasized that the model elaborated by Modigliani and Miller in 1958 is a theoretical version which has no solid empirical basis. Subsequently, Modigliani & Miller, in a specialized paper published in 1963, handled the issue of capital structure in the taxation hypothesis, emphasizing the effect it has on debts and own capitals in an indebted enterprise and in a debt-free enterprise. As well, in case of applying taxation, the enterprise’s financial structure cannot be neutral anymore, because the debt, which is deductible when calculating the taxable profit, the average weighted capital cost in an indebted enterprise is decreased as a result of fiscal savings, and in this case the financial structure indeed influences the company’s value

There are many research achievements in corporate finance field, mainly including: capital cost analysis, financing preference analysis, capital structure decision, the relationship between capital structure and company performance. In the research of capital cost analysis, the capital cost of listed companies in China is mainly calculated by capital asset pricing method in classic corporate finance theory and Modigliani and Miller average cost pricing method. In the research of financing order and capital structure, most of them are empirical studies, and most of them discuss the possible economic influence variables according to the western classic corporate financial model, and then establish the model to conduct the measurement test. In the analysis of the empirical results, the key point is also to judge whether the financial decision-making behaviors of listed companies in China conform to the conclusion of classic corporate finance theory.

This chapter studies the difference between the theoretical premise of western corporate finance and the corporate finance theory in China. The authors construct an econometric model for corporate gov-

ernance mechanisms adopted by 150 firms on the newly established Growth Enterprise Market (GEM) in China. The main conclusions of this study are as follows: the cost of capital of listed companies in our country is declining, listed companies have a strong preference for equity financing, on the capital structure of the factors, in addition to capital costs, industry factors, but also includes the size of the enterprise, profitability, business growth and other factors. However, in the above studies, institutional constraints on the nature of the economy and the external economic environment are often overlooked, and the impact of external factors is not controlled.

This chapter is structured in the following way: in the first section, the authors will introduce a brief outline of the main dimensions of the evolution regarding the corporate finance theory; in the second section, research methodology will be discussed; in the third section, the results of the study will be discussed; finally, the authors will argue the conclusions and will presented this paper's limitation.

BACKGROUND

In time, several researchers (Stiglitz, 1969; Jensen & Meckling, 1976; Jensen, 1986; Myers & Majluf, 1984; Baker & Wurgler, 2002) also emphasized other aspects of the theories related to capital structure, with reference to costs due to lack of liquidities, bankruptcy costs, agency costs, asymmetry of information, etc. The capital structure can decrease the agency costs, but achieving such an optimum capital structure which decreases the agency costs and also ensures the financing resources is a rather ideal aspect.

Regarding the grouping of factors which determine the capital structure, several specialized works among which there is the work of Hermanns (2006), two categories of factors are emphasized: external factors and enterprise specific (internal) factors. The external ones take into account economic growth, the size of inflation and the average interest rate. Also, in the specialized studies of many authors, internal factors are emphasized in terms of the achieved profitability (Wu, Gao & Peng, 2003), enterprise size (Rajan & Zingales, 1995), assets' tangibility (Titman & Wessels, 1988; Rajan & Zingales, 1995; Fama & French, 2002; Nivorozhkin, 2004; Daskalakis & Psillaki, 2008), occurrence of enterprise bankruptcy (Su, D. (2005).

In the statistical models elaborated by Booth et al. (2001) and Rajan & Zingales, (1995) certain differences were emphasized between the financing behavior of enterprises in developed countries and the behavior of enterprises in emerging countries, which were explained in terms of the nature of correlations among specific enterprise factors and their level of indebtedness (Booth et al., 2001; Chen, 2004).

A series of studies indicates as well that corporate governance may become an important factor to the dividends policy, indicating a positive correlation between the allocation of dividends and the good practices of corporate governance of the respective company (Kowalewski, Stetsyuk, Talavera, 2007; Wang & Guo, 2011).

In one of his studies (Mitton, 2004), the author emphasizes that companies with solid corporate governance standards can pay higher dividends. These companies are more profitable, and higher profitability explains the high levels of dividends. Likewise, the "positive relationship between corporate governance and dividend payment is found firstly in countries with a strong protection of investors, emphasizing the fact that corporate governance at company level and the protection of investors at country level are complementary rather than substitutes."

In the studies performed by some authors a series of factors are emphasized which can lead to adopting corporate governance codes in countries with emerging economies, such as: "the increase in the amount and the nature of financing structures which companies have access to, the decrease in capital

cost and the increase in company value, the increase in operational efficiency due to efficient allocation and management of resources, the more effective operation of financial markets” (Claessens & Yurtoglu, 2013; Cuomo et al., 2016).

In the opinion of authors Agrawal, Catalini and Goldfarb (2015) a corporate governance mechanism, if applied correctly, leads to “limiting the managers’ various discretionary actions taken in order to increase or decrease the share prices, and also to correct financial reporting, which brings along credibility to investors”. Moreover, the corporate governance mechanism would also lead to “motivating” managers into increasing the enterprises’ long-term value (Eisenhardt, 1989).

In the past decade, the number of studies on corporate governance has increased at global level, including Asia. Some of these studies are based on ideas inspired from the principal–agency theory. Authors (Shleifer & Vishny, 1997) emphasize the fact that managers, although they are “agents” of the shareholders, can also have interests which are incompatible with the principle of maximizing the overall value of the company, as principle of healthy financial management.

Authors (Chen, Cheong & Rasiah, 2016; Morek & Yeung, 2014), in a recent study, research the influence of corporate governance during the state enterprises’ reform period in China. An issue which is increasingly debated regarding the internationalization of enterprises in China is the fact that a large number of these enterprises are state enterprises, and the principles of corporate governance are difficult to implement. Furthermore, the listed company’s debt constraint is a kind of soft constraint. There are many non-economic factors in the company’s bankruptcy mechanism, and the administrative interference of the government has a great influence on the bankruptcy mechanism (Guney, Li & Fairchild, 2011). Also, the lender as the creditor is often excluded from the bankruptcy liquidation. In addition, there is no vote on the liquidation of an enterprise’s property (Ding, Nowak & Zhang, 2010). Due to the government financial guarantee (avoid bad debt), so the creditor banks have neither the ability nor the motivation to carry out the control of financial distress companies.

The maximum statutory tax rate of corporate income tax in China is 33%, but the percentage of the statutory tax rate of 33% of listed companies implementing the whole is very small (Yuan, Xiao, Milonas, & Zou, 2009). Generally, the preferential tax rate and many non-tax concessions are available. The statutory tax rates of listed companies in different industries, regions and scales are distinct. In this case, it is difficult to judge the tax.

On the other hand, other authors (Huang & Wright, 2015; Kling & Weitzel, 2011) identified a series of elements (company characteristics, the effects of industry and corporate governance mechanisms) which favor the internationalization of these companies, reaching the conclusion that cross border mergers and acquisitions lead to increasing share value, but enterprises which are the property of the Chinese state achieve too few cross border mergers.

In one of his papers, author (Li, 2007) emphasizes the recent changes which have occurred in China such as those related to property structure and the corporate governance practices, arguing that enterprise performance and also efficiency can be influenced significantly by the various market conditions. Also, a successive transformation of property and the introduction of corporate governance practices are almost impossible to achieve without there being mutations once the markets are re-launched in order to operate sustainably.

Despite all progress made by China in terms of re-balancing the economy mostly, we must still take into account the lack of transparency, the industrial policies, the still dominant position of state enterprises and a series of non-tariff measures which discriminate against foreign companies (Qiao, 2013).

Yet, the introduction of the new foreign exchange mechanism in 2015, and the less tight regulations regarding the purchase of shares with level effect could lead to an increased volatility of share markets

in China (Wei, 2017). Thus, the consolidation of the rather frail corporate environment in the past years could have new meaning in the process of reforming and liberalizing this country's economy.

RESEARCH METHODOLOGY

The empirical research builds on sample of 150 listed firms, using data from the Chinese Stock Market and Accounting Research (CSMAR) database for the financial years 2012- 2016. This analysis is based on the information discovered following the documentation process, by means of comparative research methods and critical analysis, supported by professional reasoning. We calculated both the market value-based financial leverage ratio and the book value-based debt-to-assets ratio as proxies for capital structure. We also analyzed, during the conceptual and empirical incursions, along with the financial risk, technical elements related to the corporate governance structure. The information's were processed using the Scientific Package for Social Sciences (SPSS) 17.0 and the making of the database structure was achieved by defining variables in Variable View.

In order to test the predictive quality of the corporate finance to forecast future operating cash-flows, the model formulated in this way is the following:

$$CF_{i,t} = \beta_0 \beta_0 + \beta_1 \beta_1 CFO_{i,t-1} + \beta_2 \beta_2 MVBF_{i,t-1} + \beta_3 \beta_3 ETS_{i,t-1} + \varepsilon_{i,t} \quad (1)$$

CFO: Operating cash-flows

MVBF: Market value-based financial leverage ratio

ETS: Executives' total shareholding

All the coefficients are β_1 , β_2 and β_3 are significantly positive at the level of 1%. In order to concretize the adoption impact of the corporate governance mechanisms on the predictive ability of the operating cash-flows and essentially on the predicative quality of corporate finance, we were based on the same steps to measure the market value for Chinese listed SMEs. The application of Hausman's specification test served to decide about the use of model fix effect or aleatory model. This test proves that the fix effect model is better adapted for the date in this context for the period before adoption of corporate governance mechanisms. The synthesis results in the Table 1exposes that the market value-based financial leverage ratio impact on the prediction of future cash-flow of exploitation is positive. As far as the executives' total shareholding, the estimations prove the positive significant impact. The same remark is indeed for the cash-flow of exploitation. In addition, the Fisher's test linked to the global validity of the model announces that it is significant.

The results show that the proportion of tradeable shares improves access to external debt and reduced the information asymmetry between borrowers and lenders, thereby facilitating better leverage decisions by the lenders. These findings highlight the need to improve the corporate governance of Chinese listed SMEs in order to facilitate their ability to access external debt from increasingly risk-averse lenders. The positive relationship found between executives' total shareholding and leverage suggest that policy makers should provide additional support and training for investors, to ensure that they play more of an active role in monitoring management.

Table 1. Synthesis of statistics related to regression of future operating cash flows

Variable	Coef	P-value
Constant	5,792	(0,000)***
CFO _{t-1}	0,2539	(0,016)**
MVBF _{t-1}	1,241	(0,000)***
ETS _{t-1}	0,155	(0,000)***
Model validity tests		
Hausman test Chi2 Prob>ch2	149,47 (0,0000)***	
test Breusch-Pagen Chi2 Prob>ch2	9,26 (0,0022)***	
Fisher test F Prob > F	8,72 (0,0000)***	
<i>N observations</i>	150	
<i>R²overall</i>	64,53%	
*** significant at the level of 1%, ** significant at the level of 5%, * significant at the level of 10%		

In spite of this study bringing, it seems that our results should be interpret with caution. Indeed, to study the predictive power of the operating cash-flows on a sample of heterogeneous enterprises may be a source of bias.

SOLUTIONS AND RECOMMENDATIONS

In interpreting the financial behavior of listed companies, it is necessary to determine who the decision-maker of a particular financial behavior based on the corporate governance structure and what is the objective function in reality and what are the constraints. It cannot be like Western classic corporate finance theory, thinking that the company is in an ideal state of corporate governance, and that financial policy-makers are the objective function of maximizing the company's shareholder value. For example, in China, judging from the corporate governance structure of a listed company, it is the core shareholder who owns the company's control right. The objective function in reality is to obtain the maximization of "control rent" (in different specific area of financial decision-making, "control of rent maximization" can be transformed into different specific goals). Constraints are the actual conditions of other interest balances and capital markets in the corporate governance structure. The correlation between CSR and profit, and how companies behave while they are experiencing losses but still carry out CSR activities have been analyzed in China. Finally, the actual financial decisions can be explained behavior. The process of developing CSR policies and the benefits from the involvement of all key actors including legislators, academia, business, and stakeholders are also important. Despite their general involvement, there is a general lack of coordination between these efforts. If we take into account the dividend rate estimate, then there is the issue of implementing concrete methods to determine the shareholders' expected profitability (Du, Jian & Lai, 2017). Thereby, majority shareholders are interested in long-term investments which do not take into account an immediate profitability per share, being willing to wait for

an increase in the shares' value in the future and for subsequent dividends. On the other hand, a minority shareholder more often than not aims at short-term profitability with immediate dividend.

In support of the major impact that regulations had in the stage of the corporate finance evolution, we propose the following solutions: solutions:

- A better delimitation of financial factors that determine the optimality of separation;
- The risk neutral valuation must require as many contingent claims be traded as possible jump levels ;
- Investors can base their decisions on information provided by the investment behavior of other crowd investors.

FUTURE RESEARCH DIRECTIONS

Through the goals set, this chapter has touched its target. The presented and analyzed issues are a synthesized part of the vast amount of information that has been developed by the authors to create the framework for underlining the importance of the theory of corporate finance in China.

Therefore, new directions of future research have been created, such as:

- Analyzing the impact of managerial decisions resulting from the adaptation of the principles of corporate governance;
- The assessment of the financial risk within a company can be made by assessing the reiterative frequencies of such events attesting the risk presence (for example, rectifying statements and reports);
- Analyzing the possibility of creating new tools for monitoring and measuring financial performance/performance based on the enterprise's financial structure.

Future research may investigate whether the corporate governance mechanisms improve firms' access to debt in other emerging economies and whether the access to different sources of debt has a resultant influence on the performance of SMEs.

CONCLUSION

Often under the umbrella of the speculation label or hidden legality operations, which aimed to attract investors to investments that are too risky and ultimately proved to be damaging to them (Huang, Boateng & Newman, 2016). Developed markets have issued, based on the rich experience accumulated in the field, a set of rules for the leadership of listed issuers that provide robust hedge against speculative operations to mislead investors by protecting their funds and hence retaining the positive nature of speculative operations.

In the study of the optimal financial decision-making of listed companies, we first need to determine what the objective function of financial decision-making is, and then different corporate governance concepts. However, with the development of modern companies in China, the company's goal is not to maximize the stock market value or maximize shareholders' interests, but to consider the interests of

stakeholders, that is, the “stakeholder theory.” Corporate governance is described as the behavior and outcome of all stakeholders and there is no internationally accepted model of corporate governance.

The results show that China is in the process of transition to a market economy, and the direction of corporate governance structure development in the future and what kind of concept to take in corporate governance are still inconclusive. Western corporate finance research is to maximize the value of the company as the goal, and its essence is still based on the investor, but also because the shareholders of the stock is fully tradable shares. Bonds of creditors can also be traded, so maximizing the value of company is the same as maximizing the company’s stock and bond market prices.

On the other hand, China has totally different situation. First, most of the corporate debt is bank loans, transactions cannot be traded, and creditors pursue the security of corporate finance and principal repayments. Second, most of the shareholders in the stock market are non-tradable shares. They can transfer a limited agreement. The transfer price is equal to net assets, so that this part of the non-tradable shareholders to maximize its value must maximize the amount of its own net assets. Thereby, tradable shares of shareholders in the market circulation of the transfer maximizing stock prices. It can be assumed that under the current control of non-tradable shareholders, financial decision-making reflects the controlling shareholder’s intention of “maximizing business control.”

In the future, with the gradual full circulation of state-owned shares, different corporate governance models will lead to different corporate financial targets. Therefore, in the corporate finance research, behavioral interpretation or the optimal design cannot leave this country’s special institutional background.

KEY TERMS AND DEFINITIONS

Capital Markets: Those financial markets, including institutions and individuals that exchange securities, especially long-term debt instruments.

Capital Structure: Is made up of the liabilities and equity of a company.

Cash Flow Financing: Short-term loan providing additional cash to cover cash shortfalls in anticipation of revenue, such as the payment(s) of receivables.

Corporate Finance Theory: Is a science that studies the flow and operation of company funds.

Decision: A person or group of persons’ social and deliberate act defining the purpose and the objectives of a certain action, the directions and the ways to achieve that action, all of them determined, according to a certain need, by a process of obtaining information, deliberation, and assessment of the means and consequences of carrying out that action.

Economic Management: The achievement of the budget objectives with minimum costs so that when the activity is completed the revenue exceeds the costs, namely there is a profit that ensures a level of profitability as high as possible both at general level and by product, department, or service performed.

Financial Instruments: Tools for managing the risk of business problems related to economic changes such as higher interest rates, higher oil prices, higher inflation, or fluctuating foreign exchange rates.

Funding Capital Assets: Assets used in a governmental unit that are part of a proprietary or fiduciary fund.

Market Value-Based Debt Ratio: Represent the book value of debt/ (market capitalization + book value of debt).

Performance Measurement: Determining how well a company or one of its subdivisions has done during the period.

Financial Education

Sergio Camisón-Haba

Universitat de València, Spain

INTRODUCTION

As defined by the OECD (2005b), financial education refers to the “process by which financial consumers improve their understanding of financial products, concepts and risks and, through information, instruction and/or objective advice, develop the skills and confidence to become more aware of financial risks and opportunities, to make informed choices, to know where to go for help, and to take other effective actions to improve their financial well-being”.

Financial education is therefore defined as a process oriented towards helping the financial products consumer develop a series of skills that enable him/her to make better financial decisions based on greater financial knowledge and better decision-making techniques (Lusardi & Mitchell, 2014). The possession of such skills has, in turn, been termed “financial literacy”.

The PISA report also pointed to the need for a homogeneous unit of measurement to assess the outcome of the educational process in terms of “literacy”. The term literacy has been defined as “the capacity of students to apply knowledge and skills in key subject areas and to analyse, reason and communicate effectively as they pose, solve and interpret problems in a variety of situations” (OECD, 2012:12). This definition clearly reflects what the focus of financial education should be: not the degree of mastery of the academic curriculum content, but the ability of young people to make informed, responsible and therefore effective financial decisions, by applying the lessons learned on personal finances (OECD, 2012).

Therefore, financial literacy implies having the appropriate knowledge, skills, behaviours and attitudes (Atkinson & Messy, 2012, ACCA, 2014:4), since all of them are necessary to make suitable financial choices and thus improve individual well-being (OECD INFE, 2015b: 5). That is, financial skills include not only the possession of financial knowledge, but also more broad-spectrum cognitive processes such as searching, comparing, contrasting, extrapolating, evaluating and applying information within a financial decision-making context.

The objective of financial education is therefore well defined: to improve personal financial well-being, with a particular focus on personal finances, but also aimed at fostering an ability to understand and manage broader and more complex aspects of the economic system. These range from the simple and most common, to more complex and unusual financial contexts, which have lasting consequences.

This article defines the concept of financial education as well as the results achieved at an international level. The article also analyses the potential consequences of higher-level financial education for citizens and financial consumers. Finally, the article summarizes the main positions for and against financial education and draws conclusions in the form of recommendations for designing and implementing financial education programmes. The article carries this out through a thorough review of the existing to date literature, as well as through a novel review of the different financial education programs carried out internationally and their obtained results.

BACKGROUND

1

Despite the vital importance of financial education and literacy, the reality is that the level of financial knowledge varies substantially worldwide.

The Global Financial Literacy Test carried out by Standard and Poor's with the collaboration of the World Bank in 2014 has revealed a worrying situation: only one-third of the surveyed adults were labelled as financially literate, in that they demonstrated an understanding of basic financial concepts such as risk management via diversification, simple and compound interest calculations, inflation and purchasing power. However, there are highly significant differences between countries in the level of financial literacy.

In a global financial environment with an ever-increasing number and complexity of financial products, an uneducated citizen is inevitably at a disadvantage when it comes to making informed financial decisions. Users who fail to understand basic financial issues often overestimate their ability to manage their personal finances; being overly self-confident makes them believe that they have a significantly better understanding of financial issues than they actually do (Arellano, Cámara & Roasta, 2014; Hospido & Villanueva, 2016; Lusardi & Mitchell, 2014).

The problem is thus twofold: the adult population shows a deficient knowledge of basic financial concepts, but also has an unrealistic perception of their level of understanding. This explains why, for example, 60% of American adults admit to not having a budget, less than half have savings for emergencies and the average family debt on the credit card is 3,000 dollars (McCormick, 2016). Or why an investigation by the Financial Services Authority (2006) concluded that 70% of UK citizens did not have provisions to cover an unexpected drop in income.

The insufficient financial capability of the adult population is also an incremental problem, which grows over time, as shown by the Financial Industry Regulation Authority with data from the National Financial Capability Study. Among the Silent Generation (those over 66 years of age), 65% saved for emergencies, only 8% used non-bank loans, and 14% spent more than they received. Millennials, meanwhile, show a radically different distribution: the percentage of individuals who save for emergencies has more than halved (32%), while over-consumption via non-bank loans has increased to 43%, and 23% of this age group spends beyond their means, spending more than what they receive as an income. This attitudinal change comes together with a collapse in the high levels of financial education, which has fallen from 55% in the Silent Generation, to 24% in Millennials.

The first international institution to promote financial literacy was the OECD, launching its Financial Education Project in 2003 in response to the growing interest of Member States in improving the financial culture of their citizens. This project culminated in 2005 with the publication of the book, *Improving Financial Literacy: Analysis of Issues and Policies*, which recommended promoting the financial education of citizens at all stages of life, in order to improve both personal and collective well-being. This publication served as a basis for managers to implement effective financial education programmes inspired by best practices and experiences at the international level. The OECD has continued to produce studies promoting the need to improve the public financial culture (OECD, 2008, 2014A, 2016).

However, it was with the outbreak of the international financial crisis in 2007 that a huge rise was seen in both financial education programmes and institutional initiatives, in response to the widely-supported thesis that financial illiteracy bore a good deal of the responsibility for triggering, or at least exacerbating, the crisis (OECD, 2009:9). In 2008, the European Parliament advocated for the establishment of a financial education network with the participation of public and private actors. U.S. President Barack Obama proclaimed April 2010 as the National Financial Literacy Month. Likewise, in 2012, the G20

showed its support for the principles of national financial education developed by the OECD International Network on Financial Education (INFE) (2012A). The suffering of the people caught up in the problems stemming from the financial crisis explains why the European Commission (2009:2) referred to the recent recession as a pedagogically usable moment because it helped direct adult consumers' attention towards financial education, in search of explanations and solutions to the problems they were facing.

The largest-scale initiative undertaken by the OECD in this field was to establish a framework for the design and implementation of financial education programmes and the general principles that should inspire them (OECD INFE, 2012A; OECD, 2013a, B, 2015b), as well as the introduction in 2008 of the International Gateway for Financial Education. The best evidence of the hugely positive response to these initiatives after the crisis has been the growth of INFE launched in 2012 by the OECD, which has attracted massive support from APEC (Asia-Pacific Economic Cooperation) and the G20 (San Petersburg Summit, 2013), among other institutions. Another broad alliance committed to funding programme evaluation is the Russia/WB/OECD Trust for Financial Literacy and Education. Concern about assessment has also led to the inclusion of a specific block on financial education in the PISA reports from 2015, following a pilot test in 2012.

The financial education programmes developed by different countries have not only proliferated in quantity but also in variety, including a diverse set of initiatives such as publications, internet portals, publicity campaigns, dissemination events and advisory services. Despite the difficulty of carrying out a complete inventory of these initiatives, as the OECD itself acknowledges (2016:34), this organization has persevered in this endeavour by promoting the International Gateway for Financial Education (www.financial-education.org) as an international reference database on the subject.

Financial education has also prompted projects on the G20 agenda, which in 2011 adopted the principles for the protection of financial consumers as a method of restoring confidence in the sector and strengthening financial stability. In January 2017, its programme of action addressed digitalization, inclusion and financial education, under the rationale that digital technologies may be a key tool for delivering financial education and ensuring financial inclusion.

FOCUS OF THE ARTICLE

The Debate Around Financial Education

The expansion of financial education initiatives and citizens' growing awareness of this subject has led to a situation where a large majority wants to learn about financial issues, even if they do not have a strong financial background.

But despite this broad social support, there is no shortage of dissenting voices regarding the introduction of financial education in schools. This has led to a lively debate on the advantages and disadvantages of such teaching, which has raised doubts even among columnists such as Tim Harford (2014) writing in the *Financial Times*, a publication that a priori might be assumed to be a defender of financial culture.

Defending the Value of Financial Education

Viewed as a form of human capital that has a cost (in the case of free programmes, it is not a monetary cost but learning does entail a cost in terms of time and effort), the optimum level of financial education will depend on each individual. Each person will invest in improving their financial capacities to the

point where the marginal costs of time and effort equal the marginal benefits. If these marginal benefits diminish because one person can benefit from another's financial advice, which compensates for their financial ignorance, the incentive to increase financial knowledge decreases. However, financial education is one of the few subjects that addresses issues that will be play a part in the lives of all people, whether as workers, savers, investors or consumers.

The specific personal benefits expected from financial education include the following:

- It has a positive impact on young people's financial knowledge. (Danes, Huddleston-Casas & Boyce, 1999; Bernheim, Garrett & Maki, 2001; Swinton, DeBerry, Scafidi & Woodard, 2007; Waldstad, Rebeck & MacDonald, 2010; Lührmann, Serra-García & Winter, 2015).
- It helps young people to understand the value of money and savings, to develop budgets that enable them to manage their income and distribute it between consumption and savings, and to keep their expenses under control (Bernheim, Garrett & Maki, 2001; Lusardi & Mitchell, 2009).
- It is a preparation for independent living because, for example, it teaches young people to manage loans to fund studies.
- It helps to plan ahead for the savings needed to meet future needs (e.g. retirement derivatives) or unforeseen situations (Lusardi & Mitchell, 2009).
- Greater financial knowledge is associated with prudent behaviours such as the diversification of investment portfolios or the prevention of over-indebtedness (Christelis, Jappelli & Padula, 2010, Van Rooij, Lusardi & Alessie, 2011, Lusardi & Tufano, 2015).
- It helps people contract products such as mortgages and loans with lower costs in terms of interest and commissions (Lusardi & Tufano, 2015).
- It offers knowledge that can prevent people from becoming victims of errors and fraud. However, more knowledge in this area may encourage greater frequency of use of financial instruments that expose people to greater risk (Otto, 2013).

The benefits derived from an effective financial education are not limited to the private sphere; some extend more broadly to the social sphere. Examples of such benefits include:

- Facilitating the development of a well-prepared citizenry, able to understand problems and their financial solutions, and who hold values related to saving, austerity, foresight and productive investment.
- Achieving social inclusion and a more participative society.

The third block of advantages refers to general economic benefits, which can be divided into four classic aspects of economic analysis; namely, resource allocation, economic stability, economic development and distribution (Domínguez, 2017):

- Benefits relating to resource allocation, as a competitive, efficient and stable financial system can play a Schumpeterian role stimulating an efficient allocation of capital between projects, helping to correct the bias that results from overvaluing present rewards compared to future ones, and establishing a more balanced economy.
- Benefits relating to economic stability, which mainly result from positive externalities due to their nature as public good. Financial education brings greater levels of transparency and security to the relationships between financial services users and financial institutions, and creates better-

prepared investors and more transparent markets. In turn, this can boost the efficiency of the financial system, preventing credit bubbles and ensuring greater protection of the users of financial services.

- Benefits from economic development, including developing capital markets resulting in greater entrepreneurship, enhancing innovation and higher economic growth (OECDINFE, 2015a).
- Benefits relating to distribution, as financial education helps to eliminate or mitigate another market failure, namely the problems of financial exclusion (Villasenor, West & Lewis, 2016:18). Ignorance of basic financial issues considerably reduces the likelihood of people's participation in the financial markets (Van Rooij, Lusardi & Akessie, 2011). The extent of financial exclusion has been estimated by Atkinson & Messy (2013) at 2.3 billion adults who work but who do not have an open account in any formal financial institution. Therefore, financial education can help to improve the economic position of the more disadvantaged social groups that often lack the resources required to access the financial system.

Despite the breadth and importance of the aforementioned benefits, which in the first cycle of research received practically unanimous support from the academic community, there have been some adverse reactions to the programmes that have called into question the effectiveness of the deployed initiatives.

Against the Effectiveness of Financial Education

A first group of critical voices has focused on the debatable effectiveness of financial education in terms of increasing knowledge in this field and shaping behaviour. On the basis of theoretical reasoning, some critics have questioned the universal ability of such programmes to solve financial problems. Willis (2011 a, b), in two highly critical articles, argues that financial education can have a null and even negative effect for two reasons: its inability to adapt to the speed of change and the complexity of financial products and markets, which non-specialists cannot fully understand; and its inability to counteract the greater marketing power of financial institutions.

On the other hand, there are still relatively few methodologically rigorous studies confirming the relationship between financial education and personal behaviour involving a greater propensity for saving and making long-term investments, as Atkinson, Messy, Radonivich & Yoong (2015) conclude in their review of the literature. Even the meta-analysis carried out by Fernandes, Lynch & Netemeyer (2014) concludes that the initiatives designed to improve financial knowledge only explain a very small part (0.1%) of the variance in the subsequent financial behaviour of the recipients of this training, and the partial effects of financial literacy decrease when using an instrument to control for omitted variables.

This criticism is timely because it has highlighted the need for rigorous evaluations of the effects of financial education programmes on the knowledge and financial behaviours of recipients, as well as on society and the economy as a whole (Domínguez, 2017). Despite this need, the number of evaluation studies in this area is fairly small. For example, in the PISA 2012 report only 18 of the 65 countries participating in the evaluation (mathematics and language) opted to assess financial literacy. Haslem (2014:50) indicates that few evaluations follow the standard requirements for experimental studies, including the use of a control group (individuals who have not participated in the initiatives), which can blur the significance of estimated impacts. Another methodological error that occurs rather frequently when appropriate econometric methods are not used is the problem of endogeneity (Lyons, Palmer, Jayaratne & SCHERPF, 2006). This can arise through errors of measurement of the dependent variable, the existence of simultaneity between the dependent and independent variables or the omission of a variable

correlated with an independent variable included in the model. The meta-analysis of Fernandes et al. (2014) confirms this risk by finding that studies analysing the relationship between financial education and financial literacy through simple correlations report much higher positive results than those that have employed techniques that prevent endogeneity problems. For all these reasons, Lusardi & Mitchell (2014) claim that few empirical studies can be considered as serious assessments of the effectiveness of financial education programmes.

The assessment of the positive impact of financial education initiatives is also extremely complicated because the variables that can be used to measure their effects (such as the delinquency rate or the volume of funding available) are influenced by a combination of forces that are hard to separate. The analysis of the effectiveness of financial education has helped to highlight the factors associated with the acquisition of financial knowledge; together with the educational system, these include other determinants related to the family environment and the personal profile of the students, which can explain 80% of the total variance of the results (Moreno, Campillo & Salas-Velasco, 2015).

Within students' personal profile, gender stands out as a discriminating variable, with both adult men (Lusardi & Mitchell, 2008) and young male students (Lusardi & Mitchell, 2009) getting better results. The student's age and whether they are native or immigrant have not resulted in significant differences in the causal models constructed with the PISA 2012 data (Cordero & Pedraja, 2016A).

The family's economic context plays an important role in explaining young people's financial knowledge, according to international evidence (Lusardi & Mitchell, 2009; Lusardi & Mitchell, 2014; Van Rooij et al., 2011, 2012). Entrepreneurs tend to impart a higher level of financial education than employees, who in turn provide more education than unemployed people (Lusardi, 2015; Trombetta, 2016).

The results of the evaluation can be significantly skewed by factors such as whether the teaching centres are participating voluntarily in the programme, the design of the course (in terms of technical adequacy of the content, structure and teaching methodology) (Waldstad, 2013), the degree of training and technical specialization of the teachers, and the characteristics of the formative action in terms of the time that should be dedicated to it and operational aspects. Some research, such as the study by Vrenning (2014:42), concludes that even a single three-hour class might be enough to boost people's financial self-confidence and help them improve their finance decisions. However, Harford (2014) questions whether such depths of financial ignorance can be fixed with a few night classes. Therefore, as Ambuehl, Berheim & Lusardi (2016:34) recognize, it is necessary to discern whether brief financial education actions can be effective. In short, as indicated by Haslem (2014:50), the quality of the financial education must be determined before its effects on students' knowledge of the subject can be inferred. Hastings, Madrian & Skimmyhorn (2012:16, 31-32), after expressing scepticism about the certainty of the positive relationship between education and financial knowledge, subsequently add that well-designed and well-implemented financial education programmes seem to have a positive impact.

The students' environment in terms of friendships, both in and outside the school, has also been analysed because it gives rise to valuable social and cultural capital. The peer effect has been shown to have strong explanatory power for student's financial knowledge (Cordero & Pedraja, 2016a), and the effect is stronger still when the school registers below-average performance (Albert, Neira and García-Aracil, 2014).

Finally, the level of financial literacy is influenced by the socioeconomic characteristics of the population, including the level of GDP per capita (Klapper, Lusardi & Oudheusden, 2015). There is a positive relationship between per capita income and financial education, but only for the top 50% of economies in terms of living standards. In these economies, 38% of the variation in the financial literacy rate is explained by per capita income.

The debate on the correlation between the degree of financial knowledge and certain practices in the management of personal finances even extends to the problems of establishing the direction of causation (Lusardi, 2011:45) and the meaning of causality. Hastings, Madrian & Skimmyhorn (2012:15) raise the question of whether it is financial education that leads to behaviours that generate better economic performance or, conversely, whether engaging in certain financial behaviours leads to better education in this field, in a manifestation of the well-known learning-by-doing effect. However, Lusardi & Mitchell (2014:34) reaffirm the thesis that causality flows from financial education to financial behaviour, citing as evidence experimental studies based on instrumental variables.

Another criticism of the early introduction of financial education in the school curriculum alludes to its limited usefulness, because of the time that elapses between receiving the financial education and having the chance to apply it: much of the knowledge acquired will have been lost by the time its use is required (McDermott, 2014; Eley, 2014).

The effectiveness of financial education is also conditioned by the student's attitude towards the subject. Both students' self-confidence (Arellano et al., 2014) and effort (proxied by indicators of perseverance) (Fernandez de Guevara, Serrano & Soler, 2014) have been identified as moderating variables of the effect of education on financial knowledge). On the other hand, financial experience (whether in managing bank accounts or credit cards) does not contribute significantly to influencing students' financial competence (Fernandez de Guevara, Serrano & Soler, 2014).

Cordero & Pedraja (2016a, B), based on the results of PISA 2012 at the international level, find a positive impact on financial knowledge only if the financial education is incorporated within other subjects rather than delivered separately. This is, of course, a surprising result, since it implies that teachers who are not specialized in the field get better results than those specifically trained in it. The potential for boosting students' academic performance with improved teacher training is very high (Waldstad, Rebeck & MacDonald, 2010). A report from Smart Tennessee (2010) estimated that the percentage of students with a grade of 70% or higher grew from 10.2% to 42.7% in elementary school, and from 2.6% to 39.5% in middle school, when comparing the situation before and after teacher retraining schemes and the integration of the educational centre in Financial Fitness for Life, a programme promoted by the Council for Economic Education.

SOLUTIONS AND RECOMMENDATIONS

The variation found when analysing the effects of financial education on acquiring financial knowledge and adopting good financial practices certainly makes it difficult to develop appropriate training programmes that meet recipients' needs and are adapted to the social, economic and regulatory changes that have occurred within the financial sector.

It is therefore necessary to establish certain principles of financial education. A good guide was the one developed by the OECD in 2005 in its Recommendation on Principles and Good Practices for Financial Education and Awareness. In that document, the OECD (2005b) has developed a list of good practices that is structured into four blocks: public action, the role of financial institutions, financial education for retirement savings and financial education programmes.

In terms of public action for financial education, good practices emphasize the need to educate students as soon as possible and to start financial training programmes at school, developing free information services and programmes that are as user-friendly as possible.

On the other hand, good practices in regard to the role of financial institutions in financial education call for financial institutions to act ethically and responsibly by informing, educating, and advising both their clients and their employees in a clear, transparent and understandable way.

With respect to good practice in financial education programmes, the OECD establishes how such programmes should help financial consumers find the relevant data and understand the pros and cons, as well as the different types of risks associated with the different financial products and services. Moreover, these programmes must be measurable, evaluable and, above all, adapted to the individual circumstances of each population segment.

Despite the difficulty in determining the skills to be developed by financial education, the 2012 PISA Financial Literacy report, which draws on the work of the OECD (2012, 2013c, 2015a), details the financial competences that 15-year-old students should have before entering the labour market or going on to further studies. These skills have been divided into four areas, which have been defined as central in most financial education programmes: money and transactions, planning and managing finances, risk and reward, and the financial landscape.

FUTURE RESEARCH DIRECTIONS

This article shows how some empirical studies have reported limited effectiveness in developing financial literacy (Peng, Bartholomae, Fox & Cravener, 2007; Mandell & Klein, 2009) as well as a lack of evidence of people developing behaviour involving a greater propensity for saving and making long-term investments (Atkinson, Messy, Radonivich & Yoong, 2015). It may thus be necessary to recognize that there is still scarce empirical evidence on the positive effects of financial education programmes on a personal level (Hastins, Madrian & Skimmyhorn, 2013).

To clarify the matter, it is necessary to separate two different, but frequently intermingled, issues. The first refers to the causal effect of financial literacy on related behaviour. The second is whether teaching people about personal finances results in greater financial literacy, which in turn facilitates more prudent and informed behaviours. In their meta-analysis, Fernandes, Lynch & Netemeyer (2014) use the term “measured financial literacy” to refer to the outcome of longitudinal studies that examine the causal relationships between the levels of financial literacy and subsequent financial decisions, controlling for theoretically relevant variables. On the other hand, they use the term “manipulated financial literacy” to refer to an experimental intervention to improve financial knowledge with the intention of generating more informed and responsible behaviours.

This meta-analysis of the empirical literature indicates that increased financial knowledge in terms of measured financial literacy has a significantly greater effect on financial behaviour than when we refer to manipulated financial literacy, explaining 1.8% of the variance compared to 0.1%, respectively. The effect of interventions to increase financial literacy on subsequent financial behaviour decreases even more when controlling for the omitted psychological profile, and in low-income individuals. It also decreases over time. The key problem seems to be that the courses do not achieve a significant improvement in students’ financial literacy, and the effect of such interventions is much smaller than that achieved with other educational actions in other domains. Moreover, the effect decays over time, disappearing after a few months.

If the conclusions of the meta-analytic study by Fernandes, Lynch & Netemeyer (2014) are confirmed, it would provide good cause to criticize the financial education initiatives developed, as they could be

considered an expensive waste of resources and because they entail opportunity costs when replacing other subjects that have proven positive results.

One of the possible explanations for the poor results reported to date by financial education initiatives could be found on its isolated implementation. By its very nature, any financial education policy should be framed within more ambitious activities that promote economic education from a global perspective. This integrating approach should be carried out through the development of basic modules of economic analysis, covering in the first place the demand and supply functions. Secondly, it should address the general functioning of the financial system, its agents and the products that in it are negotiated. Finally, the market regulation should complement the training of its agents, encompassing both state regulation and self-regulation by the so-called “invisible hand”; as well as the functional distribution of income and its effects on the personal distribution of income.

CONCLUSION

Although the empirical evidence presents certain gaps, this article shows that the most obvious conclusion to be drawn is that financial education is an essential element for the development of a financially-educated and responsible society.

Even so, the design of curricular content and training programmes must take into account the particular features addressed above, as well as the elements of a personal, family, economic or social nature that have a significant impact on the viability and effectiveness of financial education.

Financial education, however, is only one of the foundations on which to build a stable financial system and a consumer base capable of financial decision-making.

The design of financial education programmes must take a broad view, which includes defending citizens’ rights and needs. Excessive interest rates, abusive lending practices, and over-indebtedness among poor borrowers have generated great concern about the concept of responsible financing and consumer protection measures.

Ethical and responsible finances are therefore an essential ingredient in the fight against poverty and in generating sustainable management strategies aimed at developing lasting and prosperous businesses that benefit society. The fullest possible application of ethics in financial and banking management is thus justified to address the problems and solutions arising from the current financial model. An adequate level of financial literacy helps citizens to understand and participate in this debate and to manage their own financial future.

Given the serious gaps and important contrasts shown at an international level in terms of financial education, the implementation of effective measures to develop knowledge and financial capabilities in the population is a crucial objective. The formation and the consequent understanding of the basic functioning of the financial system will create more responsible consumers, that will make better decisions, involving both their own individual level benefit, as well as that of the society as a whole.

KEY TERMS AND DEFINITIONS

Behavioural Finance: Born from the union of psychology, traditional economy and neuroeconomy, behavioural finance study investors' psychology while making financial and investment decisions.

Ethical Finance: A financial system that seeks, not only purely financial returns, but also qualitative outcomes, reflection ideas from faith, social, environmental and governance theories.

Financial Competences: Knowledge and understanding of financial concepts, as well as skills, motivation and confidence to apply and understand that knowledge, in order to make effective decisions in a variety of financial contexts.

Financial Consumer: Any client, user or potential customer of the products or services offered by financial entities.

Financial Literacy: The capacity of students to apply knowledge and skills in key subject areas and to analyse, reason, and communicate effectively as they pose, solve, and interpret problems in a variety of situation.

Personal Finance: The management of money and financial decisions for a person or family including budgeting, investments, retirement planning and investments.

An Overview of Diversities in the Use of the Profit and Loss Statement

INTRODUCTION

The main objective of any economic activity is considered to be the «performance», and this objective has proven to be quite difficult in regards of finding an example for it (Caylor, 2010; Ribeiro, Shan & Taylor, 2019). Recent studies have shown that in the financial information market, the “most” popular product is the profit and loss account because it shows whether or not the enterprise has achieved its basic objective of achieving an acceptable return (He et al., 2017; Hou et al., 2015). Undertakings have the possibility to add to the profit and loss account other items, rows, titles and subtotals when an International Accounting Standard requires it or when such a presentation is required for a true presentation of the financial results of the enterprise. The criteria to be respected in this case are the materiality threshold and the nature and function of the different components of income and expenditure.

In the context of the expansion of transnational companies, users of financial information are interested in the performance of the enterprise determined not on the basis of the accounting result but of the economic result (Jackson & Liu, 2010). This latter indicator cannot be accounted for by the profit and loss account because it has a more comprehensive structure than the accounting result, including items that do not translate through the profit and loss account. Users of financial information are interested in information that the profit and loss account cannot provide (Dennis, 2014). In order to meet their informational needs, decision-makers need to turn to new sources of information (Amira & Nuha, 2019). That is why the accountancy profession is called upon to create new tools to remove the information limits of the financial statements. The statement of changes in equity and the cash flow statement are the “new products” of the accounting offer (Ball, 2013). The statement of economic outturn should include the effects of all transactions and events occurring during the year, whether or not related to current operations, and which have an impact on equity (excluding shareholder or associate and distributor contributions). Also, gains or losses accounted for during the year, realized or unrealized, exceptional or extraordinary, participate in the performance of the enterprise and should therefore be included in the statement of comprehensive income (Timbate & Park, 2018).

On the other hand, given that companies can choose their accounting policies within certain limits, the results obtained reflect their objectives and not the reality (Stein, 2019). In this situation, is the outcome credible and relevant? The objectives of accounting policies differ according to the size of the enterprise and the economic environment in which it operates (Ahrens, 2008; Rozenbaum, 2018). As

DOI: 10.4018/978-1-7998-3473-1.ch011

an example, it is possible to mention the reduction of the published losses, the decrease of the taxable profit, the increase or decrease of the current result, the increase or the decrease of the profit to be distributed, the temporary arrangement of the accounting results in order to reduce the risk perceived by the financial environment.

Many of the reported deficiencies were corrected during the reform (Barth et al., 2008; Cahan & Sun, 2015; Lukka, 2010). Moreover, the principle “nothing is perfect, everything is perfect” also works in accounting. In our opinion, any accounting system, however modern, converging with International Financial Reporting Standards, will never be perfect, because the world economy and, implicitly, the national economy is constantly changing (Richardson, 2011). New trends, new informational needs are emerging, and they pose a challenge to the accounting system and an invitation to reflection for accountants (Chen et al., 2017). The present chapter intends to identify the construct of a set of factors that influence the Profit and Loss Statement in the context of scarce and expensive resources.

This chapter is structured in the following way: in the first section, the authors will introduce a radiography of the current situation regarding the profit and loss account in accordance with the International Accounting Standard; in the second section, research methodology will be discussed; in the third section, the results of the study will be discussed; finally, the authors will argue the conclusions and will present this paper's limitation.

BACKGROUND

Regardless of the international accounting standard, the notion of performance in accounting has a generally accepted first acceptance. Accounting in the field of performance has first and foremost the notion of profit. Given the recent history of scandals involving accounting conduct, the credibility of the public accounting profession has dropped significantly, losing one of the core responsibilities of the professional accountant (Ribeiro, Shan & Taylor, 2019). More recent research in the field suggests that there is a growing interest in studying the ethical conduct of professional accountants (Li et al., 2017). Moreover, since the 1980s, several institutions have encouraged education in accounting ethics, and today it has come to the fact that it has been present in schools since the beginning of the accounting profession (Doukakis, 2014; Alzola, 2017). However, the accounting scandals that took place in the 2000s prove that greater emphasis is needed on the Profit and Loss Statement, but also on improving the codes of ethics (Bettner & Kate, 2013). Thus, it is noted that, the Profit and Loss Account was viewed as a complement to the information provided through the Balance Sheet, but it can be said that there has always been a fight of primordially between the Balance Sheet and the Profit and Loss Account in providing useful information to those who make decisions. Thus, the development of the corporate form of the entities brings to the fore the utility of the Profit and Loss Account in the financial reporting by increasing the interest for the performance of the entity, for the dynamic information and the decrease of the interest for the historical costs and for the punctual, static information. Despite the increased interest in this issue, there are certain deficiencies in the principles, virtues, values and rules that undermine the credibility of the accounting profession (He et al., 2017).

As the economy develops, the main interest point, performance-wise, shifts from revenue towards the profit described in the Profit and Loss Statement (Brown, 2010). This reflects the value fluxes that interacted with the increase or decrease of the wealth of the company at a certain period of time. So, the profit and loss statement highlighted the success of a company required for its survivability, or its failure to stay on the market (Khan, Khan & Elshareif, 2018).

As the financial markets are in continuous expansion, investors are becoming the privileged receivers of the financial information (Holthausen & Watts, 2001). In our opinion, in this case, the profit and loss statement becomes the main tool because it provides all the required information for the past and future performance evaluation, and also for the determination of the future cash flow risks. Also, based on the information reflected by the profit and loss statement, a pertinent analysis is created for the company's performance, a verity of indicators are calculated, either in a specific moment in time, followed by their interpretation through comparisons, either throughout a longer period of time, but correlated with certain statistic procedures.

In continental accounting, the steps of finding the result of the exercise are in close connection with the company's revenue and cost structure, while the Administrative Intermediary Balances are calculated (Li, 2010). These indicators allow comparisons throughout time in the same company or between companies. The Administrative Intermediary Balances start from the idea believing that a company is a place of turning goods into other goods, entries in exits. These transformations are done by using production factors, labor, public capital (goods and collective services), financial capital without risk and financial capital with risk. The appreciation over informational risk depends on the skills of the individuals in charge of the processes to assess the informational impact on the financial statement, on the company's performance (Schleicher et al., 2010). In consequence, the analysis of the communication system and the dialogue frequency stand for a variable that can be used in appreciating the informational risk level, as the communication frequency is inversely proportionate to the risk level.

Special attention is also given to the IASB because "information on an enterprise's performance, especially its profitability, is necessary to assess potential changes in the economic resources that the enterprise will be able to control in the future [...] which are useful in assessing the firm's ability to generate existing cash flows [...] and to formulate judgments about the efficiency with which the enterprise can use new resources" (Parker, 2012).

When preparing the financial statements, the management of the enterprise should analyze the firm's ability to continue its business. Financial statements must be prepared on a going concern basis, unless the management either intends to liquidate the enterprise or ceases business, or has no realistic alternative but to do so (Ramanna, 2008). If there is uncertainty about the business going on, it must be highlighted. Cases where the financial statements are not drawn up on the basis of accrual accounting must be highlighted alongside the basis on which they are prepared and the reason why the enterprise can no longer continue its business.

The flexibility of the provisions of the Fourth ECE Directive, concretized through the four models of presentation, as well as the possibility of choosing them by companies, is the expression of the conciliation of cultural differences between the countries of the European Union (Barth et al., 2014). French companies prefer the presentation of the profit and loss account in the form of an account, with the classification of expenses and incomes by nature, while Anglo-Saxon companies interested in meeting the information needs of investors prefer the drafting of the profit and loss account with the classification expenditure by function.

RESEARCH METHODOLOGY

In order to achieve the research objective, we resorted to the conceptual analysis of reviewing the purposes of the Profit and Loss Statement in line with the International Accounting Standards, as well as to its quantitative assessment (Yung & Root, 2019). This analysis is based on the information discovered

following the documentation process, by means of comparative research methods and critical analysis, supported by professional reasoning. We also analyzed, during the conceptual and empirical incursions, along with the risk related to socio-human factors (for example, communication process, formal and informal environment, human behavior), technical elements related to the Profit and Loss Statement.

The IASB's general framework provides for the preparation of the (profit and loss) account under the accrual accounting and consequently the release of cash flows through this document can only be achieved by processing the information contained therein, i.e. converting revenue and expenditure into receipts and payments (Barth, 2013). Financial statements prepared on the basis of accrual accounting respond to the information needs of users by providing information "not only about past transactions that generated revenue and payments, but also about future payment obligations and resources on future receipts and payments" (Byard et al., 2011).

The disclosure of US economic results is treated by the American Accounting Standard FAS 130 "Reporting Comprehensive Income" issued by FASB in June 1997. This accounting rule is opposed to all US companies preparing financial statements, except for those that do not have items that do not translate into the profit and loss account and therefore have a direct impact on equity (Baker & Bettner, 1997). Under this rule, items that do not transit through the profit account, but have a direct impact on equity, need to be detailed in a financial statement of similar importance to the others. The cumulative balance of these items should be presented in a separate line of equity, reflected in the balance sheet.

In order to avoid the double counting of elements (included both in the net result and in the economic outturn), FAS 130 allows some adjustments to the overall result of the last financial year (reclassification adjustments), such as adjustment of the economic outturn of the last financial year with the earnings on other investment titles that were included in the net result of the current exercise, but also with the other items of economic result in the form of dormant earnings during the year in which they were ascertained (Allen & Ramanna, 2013). Such adjustments may be presented in the financial statement of the financial result or in the notes.

According to the documentation made, the adoption of the Fourth Directive by the Member States of the European Union generated an abundance of profit and loss account models (Table 1). In countries like Belgium, France, Italy, Portugal and Spain, it is illegal for companies to publish their profit and loss accounts in a list format with the classification of expenses by function. Even among the countries that allow the use of the four models, there are different variants of their use. The UK has adopted all four models for the presentation of the profit and loss account. UK companies may opt to present the profit and loss account using a cost analysis either by function (costs are broken down into costs of sales, sales and administrative expenses), either vertically or horizontally or by nature (expenses materials, wage costs, external costs, depreciation costs) in a vertical or horizontal format. However, most accountants are not familiar with the profit and loss account model, vertically and horizontally, with the classification of expenditure by nature.

Looking at Table 1, we wonder why there are so many European countries that prefer to model their profit and loss account with their vertical or horizontal format analysis for their business companies.

A first argument can be a historical accident. German influence has been reflected in French accounting since the Second World War by introducing an accounting plan. Subsequently, France influenced the development of the accounting plans in Belgium, Spain and Portugal.

The second argument concerns the simplicity and transparency of the "by nature" format, although it is more detailed than the "by function" format (Andon et al., 2007; Christensen, Pei, Pierce & Tan, 2019). The format "by nature" only requires the analysis of operating expenses, such as material expenses, external expenses, labor costs, and depreciation expenses. For companies having an object of

Table 1. Models of profit and loss accounts throughout European states

	Function wise		Nature-wise	
	Vertical	Horizontally	Vertical	Horizontally

Sweden	O	x	O	x

O Allowed by national laws, x Banned

activity, it is not necessary to use a method of allocating indirect costs. The transparency of this format is due to the fact that there are no internal company decisions to be made on the basis of the accounting data and the policies used to calculate the cost of sales and the gross margin (for example, the choice of the depreciation method). Most countries requesting a “by nature” presentation also have account plans (Chen et al., 2010). Their role is to require commercial companies to maintain account balances in accordance with the national accounts plan.

The tax authorities in those countries may use the profit and loss account as a starting point for the valuation of the liabilities tax on the idea that the link to the balance symbols is transparent (Damayant, 2013). Perhaps the most relevant argument in favor of using a “by-nature” format is that this model provides the information needed to compile macroeconomic statistics. For example, in France, where the state has always been involved in business, a privileged user of financial information justifies the choice of “by nature” format. By imposing this format, the state can obtain comparable information on the added value of all enterprises that aggregate gross domestic product and other derived statistical information.

In Romania, the classification of information in the profit and loss account was based on the criteria of the nature and heterogeneity of the economic and financial transactions carried out by the enterprise (Florou & Pope, 2012). The accounting reform, started after 1990, materialized in the Accounting Law no.82 / 1991 and the Implementing Regulation approved by H.G. no. 704/1993 introduces a profit and loss account, mainly inspired by the Fourth Directive of the European Economic Communities presented in a list form, with the structure of revenues and expenses by nature. This important evolutionary step was carried out in a context that had not existed until then, namely the transition from the model of the super-centralized economy of the communist type to the market economy. This explains the appearance of controversy over the fairness of the chosen model, but in our opinion, this variation corresponded to the informational needs of the main recipient, at that time, the state.

Regulations approved by O.M.F.P. no. 3055/2009 represented a reference point since they reflected the “accounting point of view” of the Romanian economy, in the new context in which Romania is a full member of the EU, but also with the obligation of full integration into this community, which implied, among others, the continuation of the process of implementing and applying the communal regulations. It also took into account the impact of the international regulations inherent in the globalization process, which, in the case of the consolidated financial statements, included the option to draw them up, according to the Regulations in line with EEC Directive VII - based on the International Financial Reporting Standards (IFRS).

As it can be seen from the comparative analysis performed, along with the accounting practices, management decisions also have a main purpose to present a different image of the result, but without changing the business situation (Soltani, 2014). The elastic nature of the outcome limits the informational value of the profit and loss account, which sometimes can be misleading. A profitable business is not necessarily an enterprise that has liquidity. Behind profitability, it hides serious treasury issues (Bentley, Christensen, Gee & Whipple, 2018).

The profit and loss account provides information on the financial flows recorded by the enterprise at the end of the financial year in the form of profit and loss. From this explanation, one can deduced that cash profits also flow through the profit account. The answer is affirmative, in the conditions of a cash accounting, and negative, if an accrual accounting is practiced.

SOLUTIONS AND RECOMMENDATIONS

In support of the major impact that these regulations had in the respective stage of the accounting evolution, we propose the following solutions:

- § A better delimitation of the financial statements of the entities according to the fulfillment of certain size criteria;
- § The express statement of the treatment of accounting errors on the profit and loss account in the case of errors related to the current exercise, namely, on the basis of the retained earnings for errors made in previous years;
- § Introducing a new section that provides users with general purpose financial statements and their informative needs, specifying the four main qualitative characteristics of the annual financial statements (intelligibility, relevance, credibility and comparability).

FUTURE RESEARCH DIRECTIONS

Through the goals set, this chapter has touched its target. The presented and analyzed issues are a synthesized part of the vast amount of information that has been developed by the authors to create the framework for underlining the importance of producing documents providing information in such a way that, regardless of the accounting model used, it is also useful for the quality of each user. Therefore, new directions of future research have been created, such as:

- § Analyzing the impact of managerial decisions resulting from the adaptation of the accounting principles to other management methods;

- § The assessment of the informational risk within a company can be made by assessing the reiterative frequencies of such events attesting the risk presence (for example, rectifying statements and reports);
- § Analyzing the possibility of creating new tools for monitoring and measuring environmental performance/performance based on the principles of other managerial accounting methods or systems.

CONCLUSION

Controversies about the information reflected by the Profit and Loss Statement have been, and are still, generated by the difficulty of accurately determining the financial situation, as well as ethical and moral aspects related to the user-company relationship, the limit between research and accounting treatment, etc.

The freedom of choice of accounting policies by companies, which leads to an increase or a decrease in the result, is, in our opinion, one of the main information limits of the profit and loss account. We have also previously highlighted some creative accounting techniques, often in line with the laws and regulations in force, which we call the “accounting engineers”. The valuation of output stocks, the capitalization of borrowing costs, the capitalization of post-commissioning expenses of tangible assets, the preferential choice of depreciation methods are just a few examples. Often used in times of crisis, we consider that these “blunts” of accounting results do not shade, cannot minimize the role and the informational value of the profit and loss account. This is because accounting engineering mitigates the company’s difficult image, but not infinite.

Such an aspect is favored by the diversification and amplification of transnational transactions that are under the impact of different accounting and tax systems. Therefore, it is important to emphasize the importance of accelerating the process of fiscality and convergence at European level and ultimately at a global level, by adopting and applying a uniform standard.

Within this context, the management tends to omit in most of the cases that the contracting of accountancy services does not mean the outsourcing of risks for the beneficiary of such services. On the contrary, it may trigger new risks that must be taken into account. For example, the outsourcing of accounting services requires a concomitant understanding of the fact that they do not exempt the Board of directors/administrator from the liability of making sure that the services, once outsourced, are carried in a safe manner, in compliance with the current regulations, so that the risks be eliminated.

From an accounting point of view, unethical conduct can be masked fairly easily through creative accounting practices, in which professional accountants find accounting methods at the law limit so as to diminish the accounting result or present a more favoring outcome to the entity they belong to. However, in this case, the accounting approaches are law-based approaches. Thus, the question arises: are these practices evidence of ethical misconduct?

KEY TERMS AND DEFINITIONS

Convergence of Accounting: The process by which accounting standards are developed in a manner that is able to lead to the same act or purpose, by showing the similarity of national, regional, international.

Cost: The money form of all material and labor expenses made by the company to produce and market material goods, execution works and service works.

Decision: A person or group of persons' social and deliberate act defining the purpose and the objectives of a certain action, the directions and the ways to achieve that action, all of them determined, according to a certain need, by a process of obtaining information, deliberation, and assessment of the means and consequences of carrying out that action.

Economic Management: The achievement of the budget objectives with minimum costs so that when the activity is completed the revenue exceeds the costs, namely there is a profit that ensures a level of profitability as high as possible both at general level and by product, department or service performed.

Financial Accounting Standards Board (FASB): Set up and develop generally accepted accounting principles.

Financial Management: A tool in the decision-making relating to the collection and analysis of information in order to increase the performance level of the economic entity.

Integrity: The prohibition amendment, by deleting or adding, or the unauthorized destruction of information; integrity refers to confidence in the data and resources of a system by which to manage information.

Neuroeconomic Perspectives for Economics

1

Torben Larsen

University of Southern Denmark, Denmark

INTRODUCTION

The rationality of economic agents is a classical cornerstone in economics. Neoclassical theory has modified the classic concept to “Bounded Rationality” (BR) recognizing that economic agents behave as satisficers rather than optimizers (Simon, 1957). Further, modern psychology questions BR due to emotional biases in decision-making. Kahneman and Tversky (1979) claim loss aversion as typical to economic decision-making under uncertainty e.g. periods of economic recession. Positive emotional bias as complacency may be as relevant as loss aversion (Galbraith, 1958 and 1967). Neuroeconomics is presented as a new positivist model of the integration of emotions and cognition to replace the outdated classical normative economics. Behavioral and macroeconomic implications are discussed.

BACKGROUND

Medline, PsychInfo and EconLit are searched for neuroeconomic studies of “Emotional Bias in Economic Decision-making. At this early stage Medline has registered a broad selection of existing literature on neuroeconomics. Table 1 presents 10 projects representing a diversity of economic domains. Emotional biases define as deviations from perfect integration of emotional preferences and rational reasoning assumed in Paretian optimization (1906). Emotional biases are classified according to type (Fear-based or Passionate biases in accordance with Luo and Yu, 2015).

The recognition of emotional biases in DM in the format of prejudices e.g. Enquiry concerning Human Understanding (Hume, 1748) is a cornerstone in “British Empiricism” giving rise to economic growth theory (Smith, 1776).

In modern time, Galbraith is pathbreaking (1958 and 1967) in behavioral economics. In the Affluent Society he finds that the level of consumption raises beyond individual preferences due to advertising. The neural rooting of this effect is now explained by neuroeconomics (Erk et al., 2002) demonstrating that advertising symbols of power and wealth increases motivation and consumption from the pre-conscious Reptile level. Further, Galbraith finds that crucial DM-errors in top-level industrial management often rely on managerial complacency which now is explained as a special risk associated with dominance of the left hemisphere (Goel et al., 2006). Kahneman and Tversky (1979) focuses the loss aversion effect related to economic crisis which is the single psychological study that has got the most attention among economists.

Due to the criticism of the simple paradigm of economic rationality the concept of behavioral economics was presented as a pluralistic research programs starting in the 60's organized around four groups of economists situated at Carnegie, Michigan, Oxford and Stirling universities and united by

Larsen 2017	Review of fMRI of Economic Choice	Risk-aversers	Risk-lovers

their shared willingness to redirect economics towards new research directions. In the first phase of behavioral economics, disciplinary economics has become heterodox in the sense that mainstream economics, economics as taught of most universities, recognizes limitations and fallacies in the paradigm of economic rationality wherefore non-orthodox contributions to economics e.g. socialism or Prospect Theory are welcomed, too. Other attempts to renew behavioral economics are reviewed (Sent, 2005). A special review of the criticism of paradigmatic economic rationality proposes “Nudging as new social relationship (Thaler and Sunstein, 2008). Nudging is based on the *libertarian paternalism* that elbowing a kind way as alternative to simple emotional kindness helps to improve rational decision-making at the level of ordinary people. In all, this represents an admirable professional tolerance among economists but is also a crucial weakening of the prognostic value of economics for a massive majority of the population needing to preview the economic consequences of their choices to make them in a responsible way.

A study of consumer behavior shows a tri-partition of economic agents (Gountas and Corciari, 2010). In this study, consumer profiles relate to brain function as indicated by the Electroencephalogram (EEG). Three different and independent studies establish “Risk-preference” as basal determinant of behavior. A panel study with 22,000 respondents to a simple scale (0 through 10) on General Willingness to take Risks finds significant correlations with important aspects of behavior as career, sports, car driving and health (Dohmen et al., 2012). A sociometric study finds significant correlation between risk-preference and personality characteristics (Frey et al., 2017). A neuroeconomic review of game trials on economic choice identifies three different levels of risk-preference (Larsen. 2017).

FOCUS OF THE ARTICLE

This article focuses a neuroeconomic model (NeM) (Larsen, 2017). NeM identifies seven different nodes across Reptile, Mammal and Human brain levels in the processing of economic choices:

1. Ventral Tegmentum (**VT**) in the pro-Reptile brain centers the power instinct
2. Anterior Cingulate Cortex (**ACC**) in the pro-Mammal brain originates affective emotions
3. Amygdala (**Am**), also in the pro-Mammal brain, centers the fear network
4. Orbitofrontal Cortex (**OFC**) in the Neocortex controls emotions as center of preferences

5. Dorsolateral Prefrontal Cortex (**dIPFC**) in the Neocortex centers Working Memory (WM)
6. Frontopolar Cortex (**FPC**) in the Neocortex centers association of rational and emotional information to plan long-term pursuit of the stronger reward
7. Ventromedial Prefrontal Cortex (**vmPFC**) between FPC, OFC and dIPFC centers over-all cognitive integration

The brain is not linear causality, but “circular” (cybernetic) interacting feedback loops (Wiener, 1948). The model of complex adaptive systems that has developed within computer science is client-server-integrator systems (Cybernetics of the Second Order):

Figure 1. Reward-seeking system (RSS) as Client

- The brain client is the Mesolimbic Reward-seeking system (RSS) including VT, ACC and Am (internal inhibition center) (Alcaro et al., 2007), see Figure 1. RSS as motivational network is operated as reciprocal to heart rate variability (HRV^{-1}) (Thayer et al., 2012) and functionalize:

Client $\sim RS(HRV^{-1})$

- The server is the Frontal Cortex, see Figure 1. Core elements of the cognitive function are the memory system centered in the dorsolateral Prefrontal Cortex (Baddeley, 2012), the capacity of association centered in the Frontopolar Cortex (Ryals et al., 2016) and the over-all cognitive integrator in ventromedial Prefrontal Cortex (Koechlin and Hyafil 2007; Camille and Griffith 2004).

By experience Neocortex develops the ability of intuitive solutions, too (Renning et al., 2013). Cognitive activity, termed Cogn, functionalize as the degree of lateralization (LAT):

Server $\sim$ Cogn(LAT)

- The Integrator of Client and Server is an overlapping node in between the two. Anatomic is the Orbitofrontal structure at the bottom of the Frontal Cortex (OFC) a good candidate. Also, OFC is the main receiver of non-salient RSS-information passing the Anterior Cingulate Cortex (Mohanty et al., 2007). Further, OFC has a cardinal ranking of utilities (Stubborn, 2005). A neuroeconomic study identifies the vmPFC-OFC-complex as a value system constantly updating the expected utility (Levy and Glimcher, 2012). Further, OFC centers the regret function (Conscience) (Camille and Coricello, 2004). The capacity of OFC to compare subjective values is explained by an internal network informing a variety of mental functions (Padua-Schloppa et al., 2006 and 2017). OFC is identified as the value or preference center integrating **RS(HRV⁻¹)** and **Cogn(LAT)**.

The classical target of economics is maximal utility arising from simple rationality in DM. The target of cybernetic neuroeconomics is maximal adaptability. Figure 2 illustrates a parabolic relation where the Server (**Cogn(LAT)**) supports the Client (**RS(HRV⁻¹)**) more and more until the peak cognition at a moderate (risk-neutral) level of risk-preference in accordance with findings in sports medicine (Hardy, 1999). Beyond the cognitive peak, risk-preference dominates reasoning e.g. as explorative choices (Daw et al., 2006).

Figure 2. Cognition and Risk-preference

A sociometric study shows that “Risk-preference” is relatively stable for individuals and correlated with major psychological traits (Frey et al., 2017). Adaptation of the general measure to specific domains may redouble the explanatory value (Frey et al., 2017). A specific domain is financial risk-preference. Financial risk-preference is operated as “Willingness to take risks in general” on a scale from 0 through 10 in a representative survey on ‘risk attitudes’ with 20,000 respondents (Dohmen et al., 2012). The coefficients of correlation (r) on important life domains are: 1) Car driving (r=0.49), 2) Financial matters (r=0.50), 3) Careers (r=0.61), 4) Sports/leisure (r=0.56) and 5) Health (r=0.48). The skewedness of the distribution is mostly due to low female risk-preference. Also, age differentiates risk willingness for both genders (Dohmen et al., 2012).

A tri-partite economic theory on expected utility during insecurity (von Neuman and Morgenstern, 1944) has dominated behavioral economics until the Kahneman and Tversky (1979) criticism of eco-

nomic rationality. The von Neuman-Morgenstern theory is that consumer behavior differentiates between convex, concave and linear utility function of income. The challenge is now to identify the connection between Temper and shape of utility function? For this purpose, a study investigates the relationship between consumer behavior and Electroencephalogram (EEG-profile) (Gountas and Corciari, 2010):

1. Persons with a weak risk-preference have relative few EEG-connections and operate as “Pragmatics”. They respond primarily to negative incentives and less to positive financial incentives (Ojokuku and Oyedokun, 2011). Some genetic variant is associated with extreme fear responses (Munafo et al., 2008). Pragmatics aim to fulfil social norms.
2. Persons with a moderate risk-preference have many lateralized EEG-connections and operate as “Rationalists”. They respond primarily to positive financial incentives.
3. Persons with a strong risk-preference have relative many non-lateralized EEG-connections and operate as “Passionates”. A prototype of entrepreneurs (Laurie-Martinez et al., 2010). Passionates respond strongly to development facilities that strengthens their self-actualization and to live in communities that are attractive to families of any form.

Pragmatics, aiming to follow social norms, represent a linear relationship between personal income and consumption. *Rationalists* searching “value-for-money” represent a concave relation of personal income and consumption due to declining marginal utility. *Passionates* respond strongly to all kind of self-actualization facilities represent a convex relationship between personal income and consumption due to endless temptations to consumption.

SOLUTIONS AND RECOMMENDATIONS

Towards a Neuroeconomic Psychology

General psychology has identified five different groups of personally (“Big Five”) by statistical correlation studies (Goldberg, 1993). Originally, the theory of “Big Five” was advanced by two Air Force psychologists, who published a technical report in 1961 which was very little known among psychologists until the 80s. 1993 Goldberg published a multifactor statistical correlation study which confirmed the “Big Five” as the common denominators of five groups of statistical related personality characteristics. The “Big Five” are defined, as shown in Table 2.

Table 2. Definition of “Big Five” Personality Traits

Big Five Domain	APA Dictionary Definition
Openness	Differences in the tendency to be open to new aesthetic, cultural, and intellectual experiences
Conscientiousness	The tendency to be organized, responsible, and hardworking; located at one end of a dimension of individual differences (conscientiousness versus lack of direction)
Extraversion	An orientation of one’s interests and energies toward the outerworld of people and things rather than the inner world of subjective experience, includes the qualities of being outgoing, gregarious, sociable, and openly expressive
Agreeableness	The tendency to act in a cooperative, unselfish manner; located at one end of a dimension of individual differences (agreeableness versus disagreeableness)
Neuroticism	A chronic level of emotional instability and proneness to psychological distress

The relationship between “Risk Willingness” and the “Big Five” is investigated, too (Becker et al., 2015). A neuroeconomic psychology model with five different profiles (whereof three in the center) is ordered in accordance with the correlation-study (Becker et al., 2015). However, the naming of the poles is revised considering the diversity of related studies. The negative pole is termed “Pragmatics” instead of “Neurotics” preferring the term of the tradition of experimental economics instead of a diagnosis. Secondly, the positive pole is termed “Passionate” referring to Luo and Yu (2015)²⁵ and the inherent correlation between intra- versus extravertedness in the APA-definition and risk-willingness (Civaia et al., 2016).

The neuroeconomic dynamics of the concluded order of economic agents is illustrated in Figure 3. A share of “Passionates” are “Intraverts” with an elevated level of cognition which is indicated by a stippled curve. The hypothesis is, that that the ability to intraversion of passion is a special gift for artists and great philosophers.

The dimensions of the axes are derived from general neurodynamic in Figure 1.

Origo is the individual baseline of passion (dopamine activity) as processed by the Fear-network (X-axis) respective the Frontal cognitive activity (Y-axis).

Figure 3. Neuroeconomic Psychology

The relation between psychometrics by the Dohmen-scale and sensitivity to the “Big Five” is complementary rather than parallel (Becker et al., 2015). The Dohmen-scale is useful for quick identification of extreme Tempers in either the negative or the positive spectrum. Based on the skewedness of the distribution of risk-preferences, a score <3 indicate a risk-averse personality while scores >6 indicate a risk-willing personality. By scores in the risk-neutral interval (3 through 6), the subjective identification

with a specific psychological profile varies in accordance with mental flexibility where open-minded are the most flexible.

Impact on Microeconomics

Florida (2002) advanced the theory of “The Rise of the Creative Class” based on demographic statistics. The core of the creative class is scientists and engineers, university professors, poets and architects, people in design, education, arts, music and entertainment, whose economic function is to create new ideas, new technology and/or creative content. The classical core of the creative class comprises about 12% of the US work force. A broader definition of the Creative Class also includes knowledge-intensive occupations with a high degree of formal education. Examples of workers in this sector are journalists, health professionals, business managers and counsellors, who are considered part of the sub-group called “Creative Professionals”. Their primary job is to think and create new approaches to problems, as creativity becomes more valued in today’s global society. The core group and the sub-group of creative professionals comprised 30% of the US work force in 2000. A follow-up study from the European Commission finds that the creative class accounts for 42% of the work force in Denmark (Andersen and Lorentzen, 2005).

A redoubling the creative class in 20 years is that surprising that it has been object to numerous critics of 1) Exacerbation of inequalities in large cities and 2) Lack of causal explanation (Peck, 2005). Risk-preference is as mentioned above operated as “Willingness to take risks in general” on a scale from 0 through 10 in a representative survey on ‘risk attitudes’ with 22,000 respondents (Dohmen et al., 2012). Statistics to decide the substance of the theory of the rising creative class is presented in Table 3.

Table 3. Demographic Distribution of Economic Agents (%)

Group (Score)	Pragmatics (0-2)	Conscientious Agreeable Open-minded (3) '4-6) (7-8)			Explorers (9-10)
Males	3	7	22	15	3
Females	10	15	21	4	0
All (before) All (today)	13	22	43 22 [®]	19 40 ¹	3

Source: Recalculation of data from Dohmen et al. (2012)⁶: The shift of “Agreeable” to “Open-minded” over time by breeding and education. The rise of political protest movements by frustrated Conscientious.

¹Andersen and Lorentzen (2005).

Table 3 shows how the share of Open-minded, belonging to the creative class is redoubled in one generation. Up to the 60s most of the “In-between group” had rationalist values. Since the 60s, liberal patterns of elevation of offspring and a rising level of education have got a large part of the Agreeable to adopt the values of Explorers raising the “Creative Class”. So, neuroeconomics confirms the substance of the thesis of Florida. A common denominator of the whole creative class is self-actualization as career goal rather than traditional maximization of status (Florida, 2002). Referring to Figure 1, this means that the emphatic Mammal level (Singer, 2007) is strengthened compared to the primitive, power-oriented Reptile level (Erk et al., 2002) representing a personal evolutionary progress. The tenets of the creative class are described as the three “T’s” talent, tolerance and technology (Florida, 2002). These qualities are most dense in larger cities and especially in quarters rich in “Street level culture” as cafes, sidewalk

musicians, small galleries and bistros. Also, Explorers prefer user-driven healthcare like yoga and meditation (Hurk et al., 2011). The creative class is definite a core group in development of the digitalized, post-industrial economy whereof the Open-minded is identified as opinion-makers (“Maverns”) with a key role in the formation of group standards (Gountas and Corciari, 2010). Open-minded is today the largest sociodemographic group – especially among the younger generations – which is a completely new quality in economic behavior. Classical normative economics has the Agreeable as key person. The special quality of Open-minded or “Early movers” is the ability to translate novel qualities in the creative class to rational values (good value for money) in the large residual group of other rationalists and their Pragmatic followers.

Human capital is the aggregate of human know-how on production which is demonstrated an independent growth factor (Schutt, 2003). The rise of the creative class means faster and better dissemination of human capital and shorter penetration-time increases economic growth.

The rise of the creative class and associated “soft” values as more open-mindedness must not be confused with the classical assumption of profit maximization as long-term key driver of market-based production and development. Profit maximization is still remaining as the typical denominator of business life in a foreseeable future although a fraction of corporations is expected to accept an extended employees responsibility in the format of adopting the formal framework of B-corporations (Rae, 2012).

Macroeconomic Implications

From a neuroeconomic point of view, reinforcement of the cognitive function by wider and better levels of education is a direct means to strengthen both Open-mindedness and Conscientiousness as indicated by stronger center-orientation in the political left- and right-wing spectrum. The absolute classical ideologies of Neoliberalism versus Socialism become less attractive compared to modern mediated forms with priority of “*Effectiveness by the market*” versus “*Equality by welfare policy*” as new complementary political poles. The European Parliament Election 2019 exemplifies that the right wing has lost majority to a coalition of social democrats and social liberals. Center-oriented democratic policies elevate policy from simple fighting of contradictory opposites to a complex state of collaboration across the center which *alienates* groups of core voters at both poles, see Figure 3/Table 3. Right-wing examples are populist voter protests as Alternative für Deutschland (AfD), Sveriges Demokraterne (SD), “Brexiters” in UK and “Yellow Jackets” in France. Internally on the center-left the social democratic movement is weakened by decreasing solidarity with traditional labor unions which loses about 1% of their members per year.

In summary, the first phase of experiences with a new complementary political spectrum from center-left (social democrats) to center-right (social liberals) indicate that the negative side-aspect of polarization dominates. This state is a direct consequence of the neuroeconomic finding that complex choices, e.g. Intertemporal Choices, split the population in rationalists and risk-aversers.

Necessary conditions for a sustainable macroeconomic development are discussed below with a view on the novel neuroeconomic political psychology:

Redistribution of Income

The neuroeconomic confirmation of the social dimension of Mankind (Sanfey, 2007) means that the classical economic issue on redistributive fiscal policies becomes central to macroeconomic policy. Despite much public focus on inequality, the global tendency for the last decades has been – also in Scandinavia - that economic inequality as indicated by the Gini-coefficient is raising with globaliza-

tion as a key driver (Petty, 2014). This tendency is driven by increasing dominance of multinational companies (MNC), see Table 4.

Table 4. Key figures on the role of MNC in the USA

- MNC parents and their foreign affiliates accounted for 48% of all US Foreign Trade 2010
- MNC Parents accounted for 40% of all capital expenditures, but only 20% of the work force 2010
- MNC Parents accounted for 73% of all Research and Development expenses 2010
- The growth of MNC have been slow some years after the 2008 financial crisis. However, from the beginning of the 1990'es through 2008 the average rate of their growth in Direct Foreign Investments (FDI) was 8% p.a. or more than the double of the rest of the economy.
- A most descriptive figure of the global dominance of MNCs, is that the Top 100 MNCs since 2009 increased their net capital with 12% p.a. while the growth of global GDP has been 2-3%

Source: Barefoot 2012 / Bloomberg/PWC, 2017.

A new moderated goal of redistributive policy eliminates poverty by a negative income tax e.g. in the format of a Universal Basic Income (UBI). The idea of UBI is to assure everybody an unconditioned level of basic income where all basic human economic needs are covered wherefore consumption beyond UBI is on the flat part of the marginal utility curve. UBI suspends work as a necessity enabling people to rely on voluntary work within the market sector or in voluntary organisations. UBI is recommended by several Nobel Prize Laureats in economics (Milton, Meade, Samuelson, Simon, Solow, Tinbergen and Tobin). UBI may be prudently implemented as 40% of the median income (e.g. 1.000 USD/Month in 2018), entitled to all adult inhabitants (18+) with Citizenship and differentiated according to age and size of household parallel to other social cash payments. Under these conditions the total budget of UBI corresponds to about 12% of GDP. In advanced economies, UBI may largely be financed by 1) annulation of federal bottom tax deduction given a payroll tax of 25%, 2) set-off in existing public cash subsidies and 3) savings on compulsory social activities.

The main criticism of UBI is the worry that too many persons are going reducing the supply of labor. Firstly, UBI are typically that low that the expected decline in labor supply is minimal. Secondly, it follows from Figure 2 that reducing stresses on Pragmatics - the group of economic agents mostly affected by UBI - will improve the quality of DM in the direction of rationality. Thirdly, UBI facilitates development of alternatives to low-skill jobs to be replaced by future digitalized robotic technology.

The dynamic effects of UBI are studied empirically in a Finnish sample with about 2000 participants in the age span 23-59 years, where the participants receive a free, monthly income of 650 USD (Kela, 2019). Empirical results are expected to be published ultimo 2018. A similar sample study runs in Ontario, Canada, from which a series of qualitative interviews with participants confirm expected positive effects (Bergstein, 2018). Neither the Finnish nor the Canadian sample show any reduction in the willingness to work in the contrary they show improved quality of life.

Environmental Protection

Neoclassical economics considers third-party effects of economic transactions e.g. pollution as externalities wherefore the Neoclassical research in environmental protection is poor. Referring to Pigou (1920), neuroeconomics – recognizing not only the interdependence of man buy also solidarity - internalizes

third-party effects and recommend a tax corresponding to the cost of society. To design an economic strategy for environmental protection, it is important that the supply elasticity of renewable energy is estimated to 2.7 (Johnson, 2011) while the demand elasticity of energy is as small as -0.4 (Small and van Dender, 2007). It is simply more effective to protect the climate accelerating the transition to renewables by Pigou Taxing than to restrict energy consumption. A Pigou tax on CO₂-emission (CET) should have the format of *tax per metric ton carbon emission* in the atmosphere and be charged at the source where carbon enters the economy, at the wellhead, mine shaft, or import terminal. The tax would ultimately cover more than 80 percent of the economy's total emission of greenhouse gas. Across economic sectors, the transition to carbon neutrality faces special problems regarding 1) Civil flights and 2) Agriculture that presupposes massive research and development investments.

However, due to the complexity of the transition to carbon neutrality, the neuroeconomic approach to political psychology previews that the technical simple CET develops too much resistance in the format of right-wing protest movements. Therefore, a more realistic but weaker second-best transition, is a hybrid transition strategy (HTS) based on collaboration between democratic politicians and leading business organizations at the level of large cities (C40). The primary contribution of national politicians to HTS is financial subsidies to infant-energy-industries as sun, wind and nuclear fission. This line of infant-energy-subsidies is already followed in many industrialized countries and followed by China, too (Dena, GIZ, CNREC and CEC 2019).

Job-related Stress

WHO warns that the world faces a mental crisis by an epidemic raise in diagnosed depressions (Markus et al., 2012). In 2020, depression will be the second leading cause of world disability and 2030, it is expected to be the largest contributor to the burden of disease. More studies link depression to stresses related to economic crisis. A study from the American Institute for Occupational Safety and Health finds that "1 of 4 American workers often or very often burned out or stressed in their job" (Sauter et al., 1999). In all, stress is today a more frequent condition than poverty in welfare economies! Stress is not specific to the bottom of society, but as relevant to the large group aiming a career of self-actualization. This turns stress into a negative third-party effect to be dealt with in macroeconomics on line with the "Green-house" - effect.

A neuroeconomic strategy to stress-management is should be based on medical science according to which the basic mental quality is endurance. The health effect of improved endurance (by ventromedial Prefrontal Cortex) by physical exercise is documented (Oaten and Cheng, 2006). Reinspection of Figure 3 feeds the hypothesis, that as open-minded already have more flexibility than the conscientious, in-depth relaxation by mantra-meditation might increase flexibility even more? More studies support the hypothesis of increased flexibility by deeper relaxation:

- Mantra-meditation is demonstrated as a general relaxation response in a series of studies at the Harvard Medical School (Benson, 1975)
- Improved Frontal cohesion by regular Transcendental Meditation (TM) is demonstrated (Travis and Arenander, 2006)
- A Meta-analysis across relaxation techniques shows a significant effect on state anxiety
- A Health Technology Assessment (HTA) of mantra-meditation, e.g. TM, concludes that mantra-meditation is a cost-effective health intervention (Larsen, 06)

- A study of personality characteristics of practitioners of meditation shows, that those already Open-minded are early movers too, in the adoption of meditation practices (Hurk et al., 2011)

Summary

Neuroeconomic political psychology predicts that the historical fight between Neoliberalism and Socialism is outdated due to stronger center-oriented political cooperation between social democrat and social liberal parties. Center-oriented politics advance research-based interventions towards global threats as 1) Increasing inequality of income, 2) Global warming and 3) Epidemic Job-related stress, see Figure 4. However, such progressive scenario is challenged by a new polarization between the political center and its poles. Violent right-wing protest movements and left-wing erosion of social democrat solidarity.

Figure 4. Neuroeconomic Impact on Economics

Future Directions of Neuroeconomics

Perspectives outlined in Section 4 are brief outlines arising from neuroeconomics. Implementation to benefit ordinary people requires more operational research. Across these specific topics, a top 3 research priority is outlined below.

Neuroeconomics and the Education of Economists

A progress report on neuroeconomics states that behavioral economics is the field where economists meet psychology (Glimcher, 2017). The present role of behavioral economists in the teaching of economics is that they complement other economic subdisciplines with modules that are supposed to involve psychological findings beyond rationalist economic man. This study takes neuroeconomics one step further to form a *Neuroeconomic Psychology* as novel foundation of behavioral economics with impact on all aspects of economics.

The primary follow-up of the present study is on this background to develop a new positivist approach to economics that abandons classical normative economics. Hopefully, the ideas outlined in Section 4 are inspiring for this purpose.

Development of a Frontline of Green Economists

Besides neuroeconomics an important domain of positivist economics must be economic ecology. Already HTS is presented in Section 4 as the new approach to carbon neutral economy. How can economists serve HTS? In mainstream economics the central contribution is development of Cobb-Douglas-based production models as the Dynamic Integration of Climate and Economics (DICE) presented by the Nobel Laureat Nordhaus (2007). This type of model is estimated by multiple linear regression (MLR). MLR assumes a stochastic mechanics where the reaction of the elements are independent of each other wherefore they can be estimated by historical data. New economics assumes a cybernetic system where all elements are coordinated to fulfil a specific goal e.g. preservation of the Ecosystem. Setting a new strong goal as preservation of the climate means that economic agents no longer are expected to follow historical behavioral patterns but has to change historical behaviors to fulfil the new goal. In support of HTS, what's relevant is a frontline consultancy network of green economists across economic domains. This represents a completely novel approach to both education and application of economists which it would be very relevant to have tested.

Neuroeconomics and Digital Social Media

E-commerce related to social media is fast growing economic sector. This means that fair competition between traditional and virtual stores is an issue of growing importance. On this background is comparative research in customer relations management (CRM) in physical versus virtual stores an important microeconomic issue. A point of departure for this research is (Ahmed, 2015). A hypothesis for this line of research is that knowledge on the neuroeconomic profile of the e-target group (Passionate, Rationalist or Pragmatic) is a big advantage in the design of customer relations.

CONCLUSION

The neuroeconomic model (NeM) presents a modern alternative to classical economics! NeM finds a functional correlation between *risk-preference* and *cognitive activity*. This interdependence is determined by the interaction of:

1. Reward-seeking across biological levels of evolution as autonomously modified by risk-aversion and functionalized by the heart rate variability
2. The cognitive function in Neocortex as functionalized by the hemispheric dominance
3. Reward-seeking and cognition is integrated within the Frontal Cortex centering ventromedial Prefrontal Cortex

Risk-preference is differentiated as weak, moderate or strong across economic agents. Each of the three types of economic agents – respectively termed Pragmatics, Rationalists and Passionates - have differentiated responses to financial incentives across economic domains as consumer behavior, job function, behavioral health and communication: Rationalists with a moderate risk-preference peaks cognitive activity. Rationalists focus solid, goal-directed solutions. Pragmatics seek social security while Passionates seek self-actualization.

Integrating the neuroeconomic model with general personality psychology (“Big Five”) reveals that the rationalist center-function differentiates in according to degree of flexibility whereof Open-minded are the most flexible and Conscientious the least flexible. In this way the relationship between neuroeconomics and personality psychology becomes complementary where the poles are identified by risk-preference while the differentiation between risk-neutral rationalists requires psychological sensitivity. The Open-minded is the modern microeconomic key agent due to her unique ability to “translate” innovative perceptions to rational (goal-oriented) arguments.

Recognition of the differentiation of risk-preferences implicates a new neuroeconomic political psychology with research-based macroeconomic policy-interventions regarding 1) Redistributive policy, 2) Environmental protection and 3) Stress-management. This means that the historical fight between Neoliberalism and Socialism is mediated into a new political spectrum where the poles are market-based effectiveness versus equality of income. However, this qualitative political progress is due to the increasing complexity of politics threatened by increased polarization between the political center and the poles.

KEY TERMS AND DEFINITIONS

Behavioral Economics: The study of the effects of psychological, cognitive, emotional, cultural and social factors on economic decisions of individuals and institutions and how those decisions vary from those implied by classical theory.

Human Capital: The aggregate of human Know-How on production, is operated by UNESCO as an index of education.

Macroeconomics: The study of key factors in aggregate economy, for example, multipliers, to guide politicians.

Neuroeconomics: An interdisciplinary approach to behavioral science between economics, neurology, and psychology.

Pigou Tax: Tax on negative third-party effects, e.g. pollution, corresponding to the costs of the society.

Risk-Aversion: An automatic response in the fear network—centering Amygdala—to salient stimuli.

Risk-Preference: Value function of economic agents formed by reward-seeking, cognitive activity, and risk-aversion. It is graded as strong, moderate, or weak and operated respectively as Explorers, Rationalists, or Pragmatics.

Stress-Management: User-driven healthcare to improve mental health e.g. physical exercise, diet and deep relaxation.

Third Party Effects: Positive or negative effects of economic transactions on persons that are not directly involved.

UBI: Basic unconditional subsidy to all adult citizens corresponding to 50% of net median income.

The Dynamics of Demographic and Macroeconomic Variables in India

“The difficulty lies not so much in developing new ideas as in escaping from old ones.” – Keynes

INTRODUCTION

These words of Keynes are very much significant in the context of this paper. Several theoretical concepts like the Phillips curve had been ruling the charts for almost half of a century. But, the question is to what extent is this model relevant for a country like India, today. Growth theory had its beginning in the years following the World War II when war devastated economies had embarked on the programme of reconstruction and development. This had called for high savings (reduction in current consumption) so that resources could be employed for investment purposes. But, in an inflationary situation, the general tendency of prices is to go upwards which has been statistically captured by the persistent upward movement of some of the aggregate price indices, viz. Consumer Price Index (CPI) or GDP deflator. Studies have shown that inflation has a highly significant negative impact on growth. Apart from causing distress for the poorer sections of the populace, the rising and variable prices also hurt the long term growth prospects by knocking the macro environment off balance. As a result, price stability figures are positioned high among the policy priorities of the Government of India. To all intents and purposes, inflation control is now considered more important than the elimination of the output gap. It is therefore important for the policy makers to know the exact relation between economic growth and inflation.

BACKGROUND

Coming to the issue of growth-employment linkage, the growth process in India shows evidence of the inability of high growth rates of output to stimulate sufficient employment opportunities. This phenomenon has been observed in India post-liberalization, since 1991. This indeed is what emerges from a more detailed consideration of the patterns of growth and employment dynamics in India. This absurdity has indeed haunted India's economy for at least half a century and has threatened the developmental policy of ensuring employment opportunities for the populace as a whole (Ghosh and Chandrasekhar, 2007). The conventional Phillips curve in essence shows the inflation-unemployment tradeoff but the question is whether the negative relation holds good for the Indian economy. Growth is incomplete in an economy where there is not enough generation of employment. Phillips (1958) in his seminal contribution had affirmed that to control inflation in an economy, employment needs to be relinquished. Subsequently, we come to the population-growth linkage and how it affects employment. Instinctively, it can be argued

DOI: 10.4018/978-1-7998-3473-1.ch013

that impacts can be both favourable as well as unfavourable. If a country has larger amount of inoperative resources, the population can supply laborers which when efficiently utilized will result in a rise in the rate of per-capita GDP growth through the generation of employment. On the other hand, an increase in population can also negatively affect the growth rate of GDP through poverty, lack of capital formation as employment generation in the formal sector has been miserable. Hence, an increase in population tends to press hard on economic resources as well as job opportunities. This paper will be looking into the fact that whether population growth affects GDP positively or negatively in the Indian context. It is also clear that there is enough simultaneity among the focus variables.

The present paper analyzes this crucial issue by building up an empirical model which highlights the liaison between economic growth, inflation rate, employment and population growth in a Simultaneous Equation System (SES) framework. The spotlight then shifts to the theoretical foundations of this analysis. Precisely, our objective is to bring out the presence of simultaneity among the focus variables in our proposed model. This is followed by the issues pertaining to the empirical model and the methodology applied. Next, the econometric exercise has been carried out which helps us to pencil in the comprehensive policy implications of this research. The paper comes to a close by resolving the fusillade of questions.

BRIEF REVIEW OF SELECT LITERATURE

Empirical evidence about the relationship between inflation and growth differs with some studies finding a negligible effect of inflation on growth (for instance Chari *et al.*, 2000), some finding a negative effect (Chopra, 2015) and others providing evidence of the existence of a positive effect (Dholakia, 1995). Theoretically, the effect of inflation on growth is largely due to the inefficient use of resources and distorted investment decisions owing to inflation (Mallik and Chowdhury, 2001). Consequently, the relationship between economic growth and inflation may even end up being bi-directional. This ambiguous liaison amid inflation and growth necessitates that though rising inflation may have associated growth costs, policy efforts to suppress inflation could even negatively affect the growth prospects. On the other hand, by tolerating inflation at higher rates could lead to higher growth. In their paper, Singh and Kaliranjan (2005) empirically analyzed the employment-growth nexus and came to a conclusion that there exists an uni-directional causality between employment and growth. Also, Khan (2007) shows that the level of employment growth has a determining effect on a given rate of economic growth from the rate of change in poverty. It is based on the findings of 16 country case studies, including, India based on data available from the UNDP and the ILO. Ahmed and Mortaza (2005) have substantiated the existence of a positive relationship between inflation and growth by examining the long term dynamics of this relationship for four South Asian countries *viz.* Bangladesh, Pakistan, Sri Lanka and India. This paper concentrates completely on the endogenous relationship as opposed to the exogenous theoretical arguments already existing in the literature. The unemployment and inflation trade off boasts of a rich literature. Coming to the latest studies in the Indian milieu, Paul (2009) observed the existence of a short run negatively sloped Phillips curve based on the data pertaining to the industrial sector in India. In a different system, while investigating the relationship between inflationary expectations and monetary policy, Patra and Ray (2010) confirmed the existence of the normal Phillips curve. In another paper, Kapur (2013) came to a conclusion that both demand and supply factors drive inflation but demand side factors have a stronger impact on inflation seen in non-manufactured products. Interestingly, inflation in non-fuel commodities is seen as a more important driver of domestic inflation level rather than fuel inflation. Similar studies in this domain include, Mazumder (2011) and Singh *et al.* (2011). Both the studies essentially validate the

existence of a Phillips curve relation in the Indian context. Contrary to this school of thought, Ghosh and Chandrasekhar (2007) have theoretically taken up the issue of growth-employment linkage by evaluating the employment performance over the same period, at both the aggregate and sectoral levels. The developments unambiguously do not confirm the existence of a negative Phillips curve in the Indian context. The reason they put forward was India's growth in the last decade being epitomized by "jobless growth" phenomenon. To provide a means of productive employment for the ongoing escalation in the labour force forms an indispensable part of the purpose of inclusive growth (Rangarajan, 2006) but studies concerning population growth in an integrated framework with macroeconomic variables are very few in number. This paper in a more comprehensive set-up has taken a modest step in incorporating both macroeconomic and demographic variables. In the very recent literature in the context of India, there are hardly any research papers that have taken up this issue of linking up the dynamics of macroeconomic and demographic variables and the associated dynamics. So, where the results stand in the context of the very recent literature is difficult to figure out. But, comparisons have been made with the already existing literature as and when required.

THE THEORETICAL CONSTRUCT

In this context, we will make use of the money market equilibrium condition. Ghosh et al. (1997) in their article had used a simple money demand function to illustrate the difference in inflation performance across different exchange rate regimes. But, we will use a slightly modified version of that theoretical construct, in a different context, with the intention of theoretically establishing a relation among the variables under consideration.

Consider, a simple money demand function and from the money market equilibrium condition –

$$\frac{M_t V_t}{P_t} = y_t^\alpha r_t^\beta; \alpha, \beta > 0 \quad (1)$$

where, M and P denote money supply and price level, y is per-capita real output, r is the nominal interest rate and V measures residual velocity controlling for income and interest rate effects.¹ In constructing this money demand function, we have somewhat differed from the above mentioned paper by incorporating per-capita real output as opposed to real output. This implies that $y = Y/L$ where, Y is the real output and L is the current population in the economy.

Taking log on both sides in equation (1),

$$\log M_t + \log V_t = \log P_t + \alpha \log Y_t - \alpha \log L_t + \beta \log r_t$$

Differentiating with respect to time, we get:

$$\left(\frac{1}{M_t} \right) \frac{dM_t}{dt} + \left(\frac{1}{V_t} \right) \frac{dV_t}{dt} = \left(\frac{1}{P_t} \right) \frac{dP_t}{dt} + \left(\frac{\alpha}{Y_t} \right) \frac{dY_t}{dt} - \left(\frac{\alpha}{L_t} \right) \frac{dL_t}{dt} + \left(\frac{\beta}{r_t} \right) \frac{dr_t}{dt}$$

$$\left(\frac{dM_t}{dt} \right) \left(\frac{dV_t}{dt} \right) = \left(\frac{dP_t}{dt} \right) + \alpha \left(\frac{dY_t}{dt} \right) - \alpha \left(\frac{dL_t}{dt} \right) + \beta \left(\frac{dr_t}{dt} \right)$$

$$\hat{M} + \hat{V} = \hat{P} + \alpha \hat{Y} - \alpha \hat{L} + \beta \hat{r} \quad (2)$$

Now, $\hat{M}$ denotes the growth rate of money supply, $\hat{V}$ denotes the growth rate in money velocity, $\hat{P}$ is the inflation rate and $\hat{r}$ is the rate of growth of the nominal interest rate. Coming to $\hat{Y}$, denotes the growth rate of output whereas $\hat{L}$ denotes the growth rate of the population. So, it is clear that the focus variables of our analysis are indeed theoretically inter-related (equation 3).

From equation (2), we can write the relation as,

$$\hat{M} + \hat{V} = \hat{P} + \alpha \left(\hat{Y} - \hat{L} \right) + \beta \hat{r} \quad (3)$$

EMPIRICAL MODEL AND METHODOLOGY

The Structural Model

We have started our analysis from the financial year (FY) 1992-93 as FY 1991-92 is an outlier year in the Indian context which may lead to biased results (see Bery et al., 2009). The structural form of the model is given below have been estimated using data over the period 1992-2017:

$$\begin{aligned} Gdpgrowthrate_t = & a_1 + b_1 Gdp_{t-1} + c_1 Emprate_t + d_1 Infrate_t + \\ & e_1 iip_t + f_1 depratio_t + g_1 poplgrowthrate_t + \\ & h_1 nomdeprate_t + i_1 adilrate_{t-1} + u_1 \end{aligned} \quad (4)$$

$$\begin{aligned} Emprate_t = & a_2 + b_2 Gdpgrowthrate_t + c_2 Infrate_t + d_2 iip_t + \\ & e_2 depratio_t + f_2 adilrate_{t-1} + g_2 poplgrowthrate_t + \\ & h_2 Moneyspgrowthrate_t + u_2 \end{aligned} \quad (5)$$

$$\begin{aligned} Infrate_t = & a_3 + b_3 Gdpgrowthrate_t + c_3 Emprate_t + d_3 Moneyspgrowthrate_t + \\ & e_3 Infrate_{t-1} + f_3 nomdeprate_t + g_3 poplgrowthrate_t + u_3 \end{aligned} \quad (6)$$

$$poplgrowthrate_t = a_4 + b_4 adilrate_{t-1} + c_4 fertlrate_t + d_4 Gdpgrowthrate_t + e_4 Infrate_t + f_4 Emprate_t + u_4 \quad (7)$$

The endogenous variables are *Gdpgrowthrate*, *Emprate*, *Infrate*, *poplgrowthrate* whereas all the other variables in our model are pre-determined variables (lagged endogenous and exogenous). In this model, we have considered the growth rate of the GDP (yearly). The employment rate has been formulated as per the definitions of the ILO. The data for the variables used, namely, GDP growth rate (*Gdpgrowthrate*), Employment rate (*Emprate*), Inflation rate (*Infrate*), population growth rate (*poplgrowthrate*), nominal depreciation rate, NEER (*nomdeprate*), adult literacy rate (*adilrate*), total fertility rate (*fertlrate*), money supply growth rate (*Moneyspgrowthrate*), index of industrial production (*iip*) and dependency ratio (*depratio*) in this task has been compiled from the Handbook of Statistics on the Indian Economy i.e. Reserve Bank of India (RBI) database, the Planning Commission yearbook and Open Government Data (OGD) i.e. NITI Aayog database after shifting the base year for *Gdpgrowthrate* and *iip* to 2011-12 and reconstructing the entire series based on 2011-12 base year starting from 1992 onwards. Note that, the unorganized sector has not been considered because of the unavailability of data. Inflation has been calculated by the Consumer Price Index (CPI). The data on the adult literacy rate was available in an interval of ten years (as per CENSUS data) so it had to be interpolated and extrapolated accordingly as per the specification. Coming to the definition of money supply that has been taken into account here is M_3 or 'Broad Money'² and the growth rate of money supply is basically the growth of M_3 .

In this empirical model, the endogenous variables are highly correlated which point towards the presence of simultaneity. There also exists a high degree of correlation among other independent variables like adult literacy rate and dependency ratio. So, does it necessarily mean that we have multicollinearity in our model? The answer is no because in such a situation where the R^2 value is high and regression coefficients are individually significant as revealed by the higher t-values, then the multicollinearity issue may never cause a very serious problem (Gujarati, 2004).

Checking Identification and Stationarity as a Prelude to Estimation

- The order condition is — $K^{**} \geq G^\Delta - 1$ (where value of one endogenous variable is set at 1 via the invocation of normalization condition;

G^Δ = Number of endogenous variables included in the i^{th} equation and K^{**} = Number of exogenous variables excluded from the i^{th} equation).

- The rank condition is — $Rank(\Delta) = G - 1$ (where, Δ is defined as the matrix consisting of the coefficients of the parameters that are excluded from the i^{th} equation of the model (both the endogenous and exogenous variables) but included in the other equations of the system and G gives the number of endogenous variables.

For Equation 4:

$K^{**} = 3, G^\Delta - 1 = 4 - 1 = 3; K^{**} = G^\Delta - 1 \Rightarrow$ Order condition is satisfied.

$Rank \Delta = \text{Min}\{\text{Row}, \text{Column}\}$ so accordingly we will be chalking it out:- $G = 3$

$$Rank \text{ of } \Delta = \begin{bmatrix} 0 & -h_2 & 0 \\ -e_3 & -d_3 & 0 \\ 0 & 0 & -c_4 \end{bmatrix} = 3; \text{ Also, } G - 1 = 3 \Rightarrow \text{Rank condition satisfied.}$$

Therefore, equation (4) is just identified.

For Equation 5:

$$K^{**} = 4, G^{\Delta} - 1 = 4 - 1 = 3; K^{**} > G^{\Delta} - 1 \Rightarrow \text{Order condition is satisfied.}$$

Rank $\Delta = \text{Min}\{\text{Row, Column}\}$ so accordingly we will be chalking it out:- $G = 3$

$$\text{Rank of } \Delta = \begin{bmatrix} -b_1 & 0 & -h_1 & 0 \\ 0 & -e_3 & -f_3 & 0 \\ 0 & 0 & 0 & -c_4 \end{bmatrix} = 3; \text{ Also, } G - 1 = 3 \Rightarrow \text{Rank condition satisfied.}$$

Here, G = number of endogenous variables = 3. Therefore, equation (5) is over identified.

For Equation 6:

$$K^{**} = 5, G^{\Delta} - 1 = 4 - 1 = 3; K^{**} > G^{\Delta} - 1 \Rightarrow \text{Order condition is satisfied.}$$

Rank $\Delta = \text{Min}\{\text{Row, Column}\}$ so accordingly we will be chalking it out as,

$$\text{Rank of } \Delta = \begin{bmatrix} -b_1 & -i_1 & -f_1 & 0 & -e_1 \\ 0 & -f_2 & -e_2 & 0 & -d_2 \\ 0 & -b_4 & 0 & -c_4 & 0 \end{bmatrix} = 3; \text{ Also, } G - 1 = 3 \Rightarrow \text{Rank condition satisfied.}$$

Therefore, equation (6) is over identified.

For Equation 7:

$$K^{**} = 6, G^{\Delta} - 1 = 4 - 1 = 3; K^{**} > G^{\Delta} - 1 \Rightarrow \text{Order condition is satisfied.}$$

Rank $\Delta = \text{Min}\{\text{Row, Column}\}$ so accordingly we will be chalking it out as,

$$\text{Rank of } \Delta = \begin{bmatrix} -b_1 & -e_1 & -f_1 & -h_1 & 0 & -h_2 \\ 0 & -d_2 & -e_2 & 0 & 0 & -d_3 \\ 0 & 0 & 0 & -f_3 & -e_3 & 0 \end{bmatrix} = 3; \text{ Also, } G - 1 = 3 \Rightarrow \text{Rank condition satisfied.}$$

Therefore, equation (7) is over identified.

Since, all the equations in the system are identified it means that the model is identified. It should be noted that before we move onto to the estimation of the model, checking the stationarity of the variables becomes necessary. To check for stationarity of the variables, we go for Unit Root Test for every individual series with multiple structural breaks³ by applying the Dickey and Fuller (1979, 1981) test statistic and Akaike Information Criterion (AIC), with trend and intercept for knowing whether the series is trend stationary (TS) or difference stationary (DS). Now, the question which can arise in the reader's mind is that — was it necessary to perform the structural break test? The answer is no but still one may attempt Bai and Perron (1998, 2003) methodology to check whether there is any structural break and if so, note the dates of such a break. Actually, Bai and Perron (2006) in a later paper have argued and as Antoshin et al. (2008) puts it, “the size and power of their tests can be significantly distorted by several factors, such as — 1) a small sample size, 2) a small break size, 3) a small segment size and breaks clustering, and 4) the use of heteroskedasticity and autocorrelation corrections.” Furthermore, Antoshin et al. (2008) tries to solve the problem of endogenous structural breaks for small sample size and break size using Monte-Carlo Simulations for at least 50 observations in a series. But, given the size of the data set used in this paper such simulations become futile and it supports the stationarity property.

After conducting this unit test we see that all our variables attain stationarity at their level values (see results in Table 1) and we move on to the estimation procedure. Since there is no question of a cointegrated long run relation, one can directly move on to derive the reduced form estimates (i.e. a function of only the exogenous and the pre-determined variables based estimates) which will eventually serve up as instruments in the process of 2SLS estimation. After deriving the reduced form estimates of this

Table 1. Unit Root Results

We use the following model to test for the presence of unit roots, $\Delta y_t = \mu + \rho t + \tau y_{t-1} + \sum_{j=1}^k \varphi_j \Delta y_{t-j} + e_t$ where, μ is the constant, ρ is the coefficient on the time trend and j is the order of lag of the autoregressive (AR) process and Δy_{t-j} captures the autoregressive moving average (ARMA) effects (Dickey & Fuller, 1979, 1981). The test process is performed under the null hypothesis of $\tau = 0$ tested against the alternative hypothesis of $\tau < 0$. If the null hypothesis is rejected, it can be concluded that there is no unit root and the data is stationary.				
Variables	Level of Stationarity	Test statistic	Probability value	Order of Integration

model, put it back into the original model to obtain the 2SLS estimates in this simultaneous equation system (SES) framework. Consequently, the problem of simultaneity gets resolved by using the 2SLS mechanism.

2SLS AND 3SLS RESULTS

Null hypothesis: $H_0: b_1 = 0, c_1 = 0, d_1 = 0, e_1 = 0, f_1 = 0, g_1 = 0, h_1 = 0, i_1 = 0$

Alternative Hypothesis: $H_1: b_1 \neq 0, c_1 \neq 0, d_1 \neq 0, e_1 \neq 0, f_1 \neq 0, g_1 \neq 0, h_1 \neq 0, i_1 \neq 0$

Here, by looking at the $P > |t|$ values in Table 2, it can be inferred that all the variables excepting one can explain the dependent variable which is *Gdpgrowthrate* for equation (4). Therefore, the null hypothesis is rejected for all the variables excepting, *adilrate_1* which does not seem to play any role in explaining the findings and the constant term has also turned out to be insignificant. *EEmprate* and *EInfrate* have done a great job in explaining the variation of the *Gdpgrowthrate*. It should also be noted that *EEmprate* and *EInfrate* are the reduced form estimates of the model. From the $P > |t|$ values in Table 3, we see that all the variables can explain the dependent variable which is *EEmprate* in this case. Therefore, the null hypothesis for all variables is rejected so all the explanatory variables have played a part in explaining the variation in *EEmprate*.

For equation (5),

Note: * denotes significance at 5 per cent level.

Alternative Hypothesis: $H_1: b_4 \neq 0, c_4 \neq 0, d_4 \neq 0, e_4 \neq 0, f_4 \neq 0$

Hence, by observing the $P > |t|$ values in Table 4, it is clear that all the explanatory variables have explained the dependent variable which is *Infrate*. Therefore, rejection of the null hypothesis for all these variables is bound to happen.

Also, all the variables have turned out to be significant in explaining the variations in population growth rate (see Table 5). The results shows that the model has fit into the data exceptionally well with R^2 estimates of 99 per cent, 92.3 per cent, 95 per cent and 97 per cent for economic growth rate, employment rate, inflation rate and population growth equation respectively, in the structural form of the model. Next, we move onto the 3SLS approach.

The 3SLS approach involves the estimation of all the equations simultaneously. Identification of all the equations is essential in this approach. The 3SLS estimator involves estimation in three stages where firstly one needs to obtain the reduced form of the model. Then, obtain the 2SLS estimates and hence obtain the variance-covariance (Var-Cov) matrix of 2SLS residuals. Finally, using the variance-covariance matrix of 2SLS residuals from the second stage, GLS is applied to the composite model to get the 3SLS estimator (Zellner & Theil, 1962). The 2SLS and 3SLS (see Table 6) results are consistent with one another as seen in this case.

INTERPRETATION OF THE RESULTS

Examining GDP Growth Rate

The author finds a simultaneous relationship among the focus variables, GDP growth rate, employment rate, inflation rate and population growth rate; significantly affecting each other. The negative sign of the lagged values of the GDP growth rate indicates that the convergence hypothesis holds good for the Indian economy as found out by Khan and Ssnhadji (2001) who obtained the convergence after including a wide range of countries. There exists a negative bi-directional relationship between employment

Note: * denotes significance at 5 per cent level.

rate and GDP growth rate. During 2004-09, India was placed on a high growth trajectory of around 9 per cent but if we compare the corresponding employment figures we see that they were astonishingly around a meager 13 per cent per 1000. The post economic liberalization period in India has witnessed the service sector becoming the principal contributor to economic growth but its contribution to employment generation has been dismal. Agriculture, still accounts for a major proportion of the employment in India. Going by the latest developments in this sector (say, the burning issue of farmer suicides) coupled with agriculture still being a gamble during the rainy season, have aggravated the problems. So, this significant negative relationship is quite obvious.

Population Growth rate is negatively related as expected from equation 3. We can see a positive and a significant relationship with the nominal depreciation rate implying that with increase in the growth rate of exchange rate (i.e. depreciation of the home currency vis-à-vis some foreign currency) the economic growth will be boosted and hence the rise. One of the reasons why this happens is because the depreciating exchange rate leads to higher reward from exports and hence higher GDP. This phenomenon can be considered to be an indication for the holding of Marshall-Lerner condition in the very crude sense of the term in the Indian context. The counter-intuitive (negative) sign of the adult literacy rate in the growth equation can make sense when analyzed in conjunction with the result of another study, which articulated that it may take about seven to nine years for the constructive effects of adult literacy to be felt on growth in India (Dholakia, 2003). So, adult literacy might positively affect growth, but only with a substantial time-lag.

High significance and the negative sign of the inflation rate parameter shows that there are huge growth costs associated with inflation in terms of income redistribution, tax structure, losing out on international competitiveness, etc., an evidence supporting the findings by authors like - Heer and Suessmuth (2009). This is the relationship being currently observed in the Indian economy and some other developing countries where higher predictions of inflation have maneuvered the decrease in the future growth forecasts. The dependency ratio parameter shows a positive sign in the growth equation, signifying higher labour productivity in countries with a higher dependency ratio. Last but not the least, surprisingly, over the study period, the index of industrial production growth has negatively influenced economic growth as well as employment rate (on emprate the impact of iip is negligible). These results hint at a below par performance of the manufacturing and mining sectors, and a decline in basic capital goods output with their current share in India's GDP languishing somewhere around 27 per cent.

Note: * denotes significance at 5 per cent level.

Actually, this means growth in India in the post globalization era, as per the results given in Table 1, has been driven by growth in consumption and as such no real growth to that extent in investments in projects, auto sales, performance of corporate houses, employment generation, factory output of the manufacturing sector, etc.

Examining Employment Rate

The GDP growth rate has turned out to be statistically significant and the negative relationship is an implication of jobless growth in India which we have discussed in the preceding sections. The population growth rate bears a significant negative relationship as anticipated. The adult literacy rate supports a significant positive relationship with the employment rate and this implies that an increase in adult literacy leads to a rise in the employment growth rate. Due to the Government of India's investment in school education, especially the Sarva Shiksha Abhiyan (SSA), there has been an increase in the number of teachers employed by the Government schools throughout the country which may be a cause of the rise in rate of employment. The dependency ratio parameter signifies that a higher dependency ratio in India is an indication of a rise in the employment rate. Phillips curve suggested a tradeoff between the rate of inflation and unemployment which could assist the government to lower unemployment at the expense of higher inflation by pursuing the Keynesian expansionary policies. The liaison between employment and inflation has turned out to be negative significantly, contrary to the Phillips curve. One of the reasons for this may be the presence of a massive informal sector in the Indian economy. The growth of employment in the informal sector is not accounted for in the GDP and the growth rate of employment in the formal sector is comparatively low (Bairagya, 2012). So, a demand-pull inflation coming from the large informal sector dominates the impact coming in from the formal sector employment and hence is leading to this paradoxical result. This establishes the fact that India follows a Keynesian system of Government expenditure. The Phillips curve relation is a long run phenomenon and data for twenty three years may not be sufficient enough to claim such a proposition but still the results are in conformity with the vast literature on the "jobless growth" phenomenon which India has been experiencing for the last ten years (since the US crisis in 2008).

Examining Inflation Rate and Population Growth Rate

The lagged value of inflation rate has a positive and highly significant relationship with inflation. Thus, the results support the adaptive inflationary expectations hypothesis. Money supply growth rate has turned out to be statistically significant thereby affecting the inflation rate. The sign of the parameter is positive as the growth of the money supply component promotes inflation. This is consistent with the concept of "Quantity Theory of Money" as argued by Ashra et al. (2004). The bi-directional link between employment and the inflation rate has already been talked about in the preceding section. The population growth rate has a positive impact on the inflation rate. Also, GDP growth rate has turned out to be statistically significant in forecasting the inflation rate. Theoretically, all these are justified because a rise in the level of population means a greater amount of consumer demand which in turn fuels up the prices. Also, the nominal exchange rate (NEER) is highly significant and thus positively related to inflation.

The significance of the general fertility rate in the population growth equation in the model has been theoretically justified. The level of adult literacy has negatively affected population growth in this study. This implies that adult literacy has acted as a catalyst in the process of population control coupled with a strong consortium of Community Health Centres (CHCs), Primary Health Centres (PHCs) and Sub

Centres (SCs) active in the execution of family planning programmes. However, the General Fertility Rate (GFR) has been on the high so the achievements of family planning programmes still remain an unresolved mystery. The recent statistics of GFR reported by the Government of India (GoI), being 3.10 per cent advocates that these are disturbing signs which warrant immediate attention as there exists a negative effect of a rise in population growth on the macroeconomic variables *viz.* growth and employment status. Interestingly, an increase in the level of income or employment opportunities reduces poverty (Ahluwalia et al., 1979; Sala-i-Martin, 2005) which indirectly functions as a catalyst in the reduction of population growth. But, the reverse causality does not hold in the model. Now, to point out the fact that poverty reduction actually retards population growth, at the basic level, the author carries out a simple correlation analysis between head count poverty levels and population growth⁴ in India for the period under consideration (*till the year 2011-12). The correlation value is 0.56 and is significant at the 5 per cent level. This supports the findings by van de Walle (1985), Islam (2004) that poverty levels in India have gone down along with population growth rates.

CONCLUSION

Every economy prospers on a strategy for faster growth of productive employment together with sustaining a stable position between growth and inflation. Despite the historically unprecedented economic performance, India continues to maintain incongruity between the rate of economic growth and the growth rate of employment (6.6 percent in 2017; unemployment rate of 6.06 per cent in February 2018). As already mentioned, a major proportion of the workers are in the non-agricultural economic activities and work in the informal sector where they tend to suffer from a massive quality shortfall in the employment conditions, in terms of, low productivity, minimal earnings, pitiable working conditions and lack of social protection measures (NCEUS, 2009). Presently, the challenge for India is to not only generate new productive jobs but also to improve the quality of existing jobs. In addition to this, India has failed to play satisfactorily in the field of controlling inflation (4.96 per cent (till July 2018)). Presently, India is going through a phase of high inflation which has cast a negative impact on its economic growth (Madhavankutty, 2018) as shown by the results of the model. So as to keep a thorough check on the rate of inflation, both the Reserve Bank of India (RBI) and the Government of India (GoI) must be more cautious in their approach. If the government recommends a policy for achieving the objectives of price stability then objectives like GDP growth and employment position must also be taken into account simultaneously. But, in India, the objectives of price stability and inflation have always been at loggerheads (Jose, 2016). The author feels that when all the aforementioned measures are implemented properly in conjunction with one another, possibly then, our much coveted dream of an economically prosperous India can come true.

The framework developed in this paper is innovative in the sense that it provides an insight into how a researcher can correlate the effects of demographic variables on macroeconomic variables. Our results have highlighted that population growth has negatively influenced economic growth in India. In the recent years, the size of the working age cohort has increased given the number of dependents but since India could not orchestrate for productive employment opportunities, the potential acceleration of growth anticipated in due course of time lead to economic deceleration. Though, we have not particularly focused on the topic of 'demographic dividend' but the results clearly bear an indication that during the period considered, India has been unable to realize the benefits stemming from demographic profile changes (Bloom, 2011; Mitra & Nagarajan, 2005). Had India been able to take advantage of the circumstances,

the story could have been different altogether. Nevertheless, ten years down the line, the inference could be different given the fact that initiatives taken by the government for generating productive employment opportunities are successful in their mission.

FUTURE RESEARCH

The novelty of this paper also lies in the theoretical justification of the fact that macroeconomic objectives in the Indian economy are mutually dependent. This experiential configuration can be broadened by incorporating variables such as fiscal deficit, savings, the trade-openness ratio and financial inclusion. Carrying out the Error Correction Mechanism and Granger Causality would have added another dimension had the time series considered been long enough, say over a 40 year span. To further comment on the long run time series properties, the researcher can modify this model by inserting a dummy — one for the pre-liberalization period and another dummy for the post-liberalization period. This implies that there will be a set of results from 1970-1990 i.e. in the pre-liberalization period and another from 1993-2017 in the post-liberalization period. Comparing such results will be indeed interesting. Another interesting extension for a researcher would be to carry out a similar exercise for other countries in Asia or across the world in a panel data set-up to see the variation in the results. These are some of the areas where this paper can be extended.

KEY TERMS AND DEFINITIONS

Census: A census is the modus operandi of methodically acquiring and recording information about all the members of a given population in a given geographic area. The term is used most frequently with national population and housing censuses; other common censuses include the likes of agriculture, business, and traffic censuses.

Demographic Dividend: Demographic dividend occurs in the process of demographic transition when the proportion of working people in the total population is high and more people have the potential of productively contributing to economic growth.

ILO: The International Labour Organization (ILO) is an agency of the United Nations mainly dealing with labour problems, particularly, the international labour standards, social protection, and work opportunities for all. At present, there are 187 member states in the ILO, 186 of the 193 UN member states plus the Cook Islands.

Jobless Growth: Jobless growth is an economic phenomenon where an economy experiences a situation of growth coupled with a decreasing level of employment.

Quantity Theory of Money: In monetary economics, the quantity theory of money states that “the general price level of goods and services is directly proportional to the amount of money in circulation, or money supply”. In its simplest form, the theory is expressed as:

MV: PT (the Fisherian Equation):

Each variable denotes the following: M = Money Supply

V: Velocity of Circulation (the number of times money changes hands)

P: Average Price Level

T: Volume of Transactions of Goods and Services

The original theory was considered orthodox among the 17th century classical economists and was overhauled by 20th-century economists: Irving Fisher, who formulated the above equation, and Milton Friedman.

Reserve Bank of India: The Reserve Bank of India (RBI) is India's central banking institution, which controls the monetary policy of the Indian rupee.

Simultaneity: Simultaneity is a specific type of endogeneity problem in which the explanatory variables are jointly determined with the dependent variable and thus, the error term is correlated with the explanatory variables.

Stationarity: The statistical properties like mean, variance, autocorrelation, etc. of such a time series are all constant over a period of time. Statistical forecasting methods generally use this stationarity property through mathematical transformations in the process of predicting how the future varies in comparison to the past. It, thus, aims to identify whether there is unit root in the time series process or not.

ENDNOTES

- ¹ The fundamental findings do not depend on any specific structure of the Money Demand function. The functional form that we have considered in our model is of the Cobb-Douglas type.
- ² M_3 = currency with the public + other deposits with the Reserve Bank of India (RBI) + demand deposits of banks + Time deposits with commercial banks (Fixed deposits, Recurring deposits)
- ³ See for details Agarwal and Ghosh (2015) to get a clear idea about multiple structural breaks in India.
- ⁴ For details on how population growth affects poverty in different levels of transitions read Merrick (2002).

The Economics of Unemployment

INTRODUCTION

U. S. Bureau of Labor Statistics (BLS, 2018) reported that America employer payrolls increased by 201,000 workers in August 2018. However, the BLS Labor Force Statistics' Current Population Survey (CPS) revealed the U.S. labor participation was only 62.7%. Furthermore, the U.S. Census Bureau CPS indicates 96,157,000 adult Americans did not work in August 2018. The unemployed included 5,534,000 individuals that wanted a job but could not find one. Additionally, 1,443,000 reported they were available for work, wanted a job, and had searched for a position the prior 12 months. However, disturbingly, 598,000 working-aged Americans said they are not available to work even though they worked the prior year. The latter included individuals whose reasons for not working were "not ascertained."

BACKGROUND

To understand America's misunderstanding regarding the actual number of unemployed adults nationally, one must understand the science of economics and its history. Economics has been defined as the science of production, services, and consumption (Minsky, 1986). Smith (1776) argued there are four types of fixed capital: (1) useful machines and instruments of trade; (2) building and means of procuring revenue; (3) improvements of land; and (4) the acquired and useful ability of all the inhabitants or members of a society. Smith expanded upon the value of a nation's inhabitants by stating that the acquired usefulness of members of a society should be maintained by education, study, and apprenticeship and that investments in workers is equal to investments in machines (Rindermann, 2008). Smith (1776) also argued that humanitarian efforts, altruism, and sympathy are an unreliable guide to moral behavior. Furthermore, he argued that people are not under the control of their passions and emotions and could not be trusted to look out for the welfare of the common man (Ashraf, Camere, & Lowenstein, 2005, p. 134, 135).

The abject poverty, inequalities, and unwinnable war that led to the Russian Revolution and the creation of the Soviet Union was built upon those principles. Karl Marx and Thomas Malthus interpreted Smith's theories to mean economic markets and prosperity should be the entitlement of all of a country's residents, not just the wealthy (Beattie, 2018). The result was the rise of Socialism, an economic model that valued the employees (producers) or over the suppliers (employers) and promoted the typical working class' ability to work as the most important and asset of a nation (Beattie, 2018, p. 1-3)

DOI: 10.4018/978-1-7998-3473-1.ch014

European socialism scientists Henri de Saint-Simon, Charles Fourier, Robert Owen, Pierre-Joseph Proudhon, and Mikhail Bakunin, however, had opinions in direct contrast with Smith's capitalistic theories (Arato, 1989). The issue was who would care for the working class to ensure they were able to prosper during times of economic growth. As a result, new voices from the West began to question both theories. Notably, Leon Walras, a French economist, tried to resolve the conflict by creating a model that used mathematical principles and statistics to create probabilities and scale to determine manage the volatility of supply and demand (Beattie, p. 6). The mixed economy theories of John Maynard Keynes rose to the top in America, and Keynesian economics, which argued government should intervene to balance economics, became the prevailing thought for decades. However, not everyone agreed with the constraint in Keynesian theory that stated that everyone who wants a job should be able to have one. This disagreement put pressure on the financial the banking and investment sections.

Minsky (1986) wrote, "There is nothing in the economic theory of either Keynes or Kalecki that points to the welfare state as the way out of the special instabilities that capitalist economies exhibit." When Keynesian economics failed to correct the 1991 – 2001 American recession, a new school of economic thought, the Rational Expectancy Theory (RET), rose to dominance. Grounded by the theories of John Muth, RET proponents once again promoted that trickle-down economics are what America's financial sector needed and promoted the idea of "natural unemployment" that argues the laws of supply and demand should determine how many people are employed based on production needs. RET argues that a "healthy" unemployment rate should range between 3% and 7% and that there is no such thing as "zero unemployment." Furthermore, RET argues that employers should have the freedom to hire only employees with certain skills sets. RET opines efforts other than what is ineffectual (Nash, 2018).

Arthur Lewis sought to bridge the gap between the competing economic theories by beginning a field of developmental economics focused on investments in human capital, which led to the creation of the Human Capital Theory (HCT). HCT proponents consider long-term unemployment as wasted human capital or the failure of a nation to transform raw human energy and power into highly productive assets capable of sustaining an economy under any condition. This theory argues the ties between investments in a nation's people (human capital) is so intertwined with investments in financial capital, organizational capital, intellectual capital, structural capital, relational capital, customer capital, social capital, innovation capital, and process capital that lack of investment in one area will negatively impact investments in the others (Edvinsson & Malone, 1997). Further, Nafukho and Brooks (2004) argue that a nation's wealth rises, and falls, on the backs of leveraged human capital.

METHOD

The literature review sought to answer the research question: *Why are so many Americans not unemployed?* The overall goal of this study is to conduct a rigorous empirical review and examination of literature focused on the economic policies that influence unemployment in America. The purpose was to provide general definitions of the philosophies and perspectives from research, theorists, and practitioners regarding unemployment and collect sufficient works to classify and code the literature for synthesis. The intent was to critically appraise the phenomena of unemployment research from a broad range of perspectives.

Cooper's (1988) Taxonomy of Literature Reviews for an integrated exhaustive coverage with selection criteria was used as the framework (Cooper, 1988). A preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P) statement and checklist was adopted to establish the

Table 1. ERIC database keyword search terms and results

rationale and scope for the review and for pre-planning the methodological and analytical structure of the literature review process.

Five steps were completed. First, the authors identified and used keywords to search for literature related to unemployment. Second, the authors searched the EBSCOHost database for works using previously established criteria. Third, the authors examined literature abstracts for relevance to the research question and to identify exclusions. Fourth, the authors weighed selected literature using a hierarchy to facilitate judgment regarding the quality of evidence using a statistical approach. Fifth, the authors used a systematic process to organize, synthesize, and prepare the findings of the review for publication, dissemination, and translation into practice.

Data Sources, Search Strategies, and Preliminary Screenings

Seven unique keyword phrase searches for English studies were conducted between October 28 through November 17, 2018. The intent was to complete the work and prepare it for publication in 2019. Keyword phrases searched were: “unemployment”, “structured unemployment”, “long-term unemployment”, “wasted human capital”, “human capital management”, “human capital theory”, and “unemployed workers.”

The EBSCOHost account was also used to search for and find four seminar study keyword Boolean searches by title and author during separate searches. The inclusion of these works in the systematic review was necessary because the classic works were of central importance to the topic and provided the conceptual framework for this study and literature syntheses. Table 1 identifies the 319,110 works identified using the keywords indicated.

Preliminary Screening Exclusion Criteria

The authors used preliminary screening (P) to narrow the focus of the review and to exclude works deemed as duplicates, not directed toward the topic, not U.S. worker-focused, or unavailable through University of North Texas’ EBSCOHost. Table 2 provides an outline of the studies excluded during the preliminary screening process.

Table 2. Literature exclusions by reason

P1: Duplicates	0
P2: Not directed toward topic	6
P3: Not USA working adult exclusive	22
P4: Not available	7
Total Literature Exclusions	35

Selection Criteria Screening

The authors identified 145 English works published and unpublished in peer-reviewed scholarly journals, conference papers, proceedings, dissertations, theses, and working papers written between 1980 and 2018 based on the thorough search and exhaustive keyword searches, and the authors read the abstracts of the identified sources. Additionally, the authors excluded several seminal studies and theoretical works of central importance to the topic based on their acceptance within the scholarly community as indicated by number of citations. Works not available through the ERIC database or not accessible through the University of North Texas' EBSCOHost were also excluded.

Data Gathering, Selection, and Organization

E2: Lacked inference clarity	3
E3: Lacked topic generality	2
E4: Lacked validity or reliability	1
Total Literature Exclusions	7

Between September and December 2018, a neutral or unbiased principal investigator determined which works would be included. The investigator used as little personal interpretation as possible while selecting relevant literature for consolidation and synthesis using a statistically valid approach.

The authors used Microsoft Office 2016 Access to arrange literature by title, authors, year of publication, participant population, sample size, primary findings, and limitations. Additionally, the authors organized the literature conceptually so that works related to the same ideas or research methods would be analyzed categorically and methodologically.

Moreover, the authors wrote the literature review for the public, specialized researchers, policy-makers, and other stakeholders to use during decision making. The intent was to also publish, disseminate, and translate the information and evidence for a wider audience if accepted and cited as evidence by the economic and socio-science bodies of knowledge.

Selection by Classification

To ensure independent and dependent variables were examined for causal relationships, the authors selected a wide variety of studies for synthesis to understand relationships between unemployment theories and variables. This study grouped subsets for analysis of interrelationships among mediators and moderator variables (See Figure 1), which identifies the groupings of coded works by classification.

Figure 1.

Figure 1 shows literature selected by study type and characteristics. This study grouped subsets for analysis of interrelationships among mediators and moderator variables, which identifies the groupings of coded works by classification.

Coding and Weights by Classification

The principal investigator coded, weighed, and assigned a value to both published and unpublished literature. Table 3 provides the ranking of the literature from “L1” to “L5” based on the determined relevance and significance of the work by classification as outlined below.

Table 4. Literature coding and weights by classification

Search Terms	Results	%
L1: Literature reviews	4	10.5%
L2: Quantitative studies	2	5.3%
L3: Qualitative studies	1	2.6%
L4: Seminal, theoretical, dissertation works	26	68.4%
L5: Governmental/economic reports	5	13.2
Total Literature Exclusions	38	

Data Extraction

Researchers extracted and synthesized relevant data to create statements by weight and quality, then combined the statements into a summative statement. The authors wrote the narratives to describe the syntheses and tables were included to display study designs, variables, outcomes, and context.

Data Analysis and Syntheses

Researchers will combine extracted data with type and present them as a coherent summary of the evidence that answers the research questions to enable researchers to draw conclusions. Descriptions of the volume and characteristics of the evidence by type, including details related to research design used, variables studied, outcomes measured, and contextual settings will be defined. The authors also provide statements regarding the consistency of evidence and summaries of relevance.

FINDINGS

The goal of this study was to integrate and generalize the information from multiple sources and identify and resolve inconsistencies or conflicts. The review seeks to answer the research question: *Why are so many Americans unemployed?*

Researchers have defined prolonged periods of unemployment as a persistent, structural phenomena (Dorsi et al., 2017, p. 164) that significantly reduces a worker's ability to find new employment (Bivens & Shierholz, 2014, p. 381; Birkenmaier, 2016, p. 202; Krueger, Cramper, & Cho, 2014, p. 229; Mutijani, 2009, para. 5) and robs them of their overall feelings of well-being and quality of life (Watson & Deller, 2017, p. 6). Moreover, unemployment can be particularly devastating to minority heads of households and other disadvantaged populations especially (Ganong & Nel, 2015, para. 5; Sherraden, 1985, p. 407). Analyses of the long-term unemployed have documented how their subjective well-being (Alexander, 2018, p. 24; Lucas, 2014, p. 386) is devalued and how this eventually leads to depression and anxiety about the future (McClure, 2018, p. 153).

While Keynesian economists feel the government has a responsibility to intervene to help ensure everyone that wants a job can have one (Keynes, 1937, p. 215; Ashraf, Camerer & Loewenstein, 2005, p. 145), the Rational Expectancy economists feel it is not the government's role to disrupt free-markets by incentivizing employers to hire (Gali, 2017, p. 37-38; Labonte, 2018, p. 38; Minsky, 1986, p. 5; Muth, 1962, p. 335). Rational Expectancy proponents continue to argue for free markets, including the rights to outsource jobs overseas to pay cheap wages and to avoid paying taxes (Janoski, 2014, p.173). These economists continue to argue for free markets even as American streets turn into crime-ridden war zones (Chiricos, 1987, p. 212).

Proponents of the Human Capital Theory, however, feel that investments in human capital makes good business sense (Beattie, 2018, para. 3; Hwang, 2017, p. 7; Nichols, Mitchell, & Lindner, 2013, p. 3). Human Capital theorists argue that policymakers should hold employers responsible for giving America's youth a fighting chance at having a decent life (Annie E. Casey Foundation, 2012, p. 15; Gould, Mokhiber & Wolf, 2018, p. 22) by investing in job training that can help American workers close their skills gaps so that they can become competitive, productive workers (Altig, 2012, para. 1; Crump, 2012, p. 6; AltigGreenstone & Looney, 20011, p. 18)

Limitations

Limitations to this study include the researchers' decision to limit searches to the University of North Texas EBSCOHost and Google Scholar databases. Another limitation was that the results from EBSCOHost were filtered by relevancy and only the first 40 results were screened. Additionally, studies published before 1980 were excluded.

DISCUSSION AND IMPLICATIONS

Over 200 years ago, Adam Smith once wrote:

“Fourthly, of the acquired and useful abilities of all the inhabitants or members of the society. The acquisition of such talents, by the maintenance of the acquirer during his education, study, or apprenticeship, always costs a real expense, which is a capital fixed and realized, as it were, in his person. Those talents, as they make a part of his fortune, so do they likewise that of the society to which he belongs. The improved dexterity of a workman may be considered in the same light as a machine or instrument of trade which facilitates and abridges labor, and which, though it costs a certain expense, repays that expense with a profit.”

Considering Smith's observations, regardless of their differences, America's economist should agree that wasted human capital or, in the context of this study, the long-term and chronic unemployed, is expensive to both families and commerce. One respected economist, Arthur Okun, used mathematical equations to prove for every 1% increase in unemployment, America's economy's Gross National Product experiences a 2% drop (Okun, 2015). Therefore, despite perceptions that job training programs are public welfare, history indicates such expenditures are investments.

FUTURE RESEARCH DIRECTIONS

Based on the findings, the authors recommend that a more expansive review be conducted to identify points of agreement and disagreement between economists related to unemployment and its impact to the economy. The research should include cost-benefit comparison of public assistance expenditures for unemployed workers compared to investments in job training programs.

CONCLUSION

The findings of the literature review infer that one would think American policymakers and businesses need look no further than the 2018 federal budget expenditures for answers. American taxpayers are paying substantial amounts for social services, (U.S. Department of Health & Human Services, 2018, p. 3), crime and incarceration (U.S. Department of Justice, 2018, p. 5), and unemployment insurance (U.S. Department of Labor, 2018, p. 2) each year, which research ties to long-term unemployment. There, the failure to consider alternatives assumes current U.S. economic policies that ignores the plight of 96 million unemployed Americans may be putting the country on an unsustainable path. The alternative appears

to be to promote investments in job training programs designed to close the American workforce's skills gap. This would represent an investment in American workers (Janoski, p. 173).

KEY TERMS AND DEFINITIONS

Cyclical Unemployment: Cyclical unemployment is the component of overall unemployment that results from economic upturns and downturns.

Economics: Economics is a social science concerned with the production, distribution, and consumption of goods and services.

Expectations Theory: Expectations theory attempts to predict what short-term interest rates will be in the future based on current long-term interest rates.

Frictional Unemployment: Frictional unemployment occurs during a period when workers are searching for new employment or transitioning from their old jobs to new ones.

Full Employment: Full employment is an economic situation in which all available labor resources are being used in the most efficient way possible.

Human Capital: Human capital is an intangible asset or quality not listed on a company's balance sheet.

Keynesian Economics: Keynesian economics is an economic theory of total spending in the economy and its effects on output and inflation.

Natural Unemployment: Natural unemployment, or the natural rate of unemployment, is the minimum unemployment rate resulting from real, or voluntary, economic forces.

Rational Expectations Theory: The rational expectations theory is a concept and modeling technique that is used widely in macroeconomics.

Unemployment: Unemployment occurs when a person who is actively searching for employment is unable to find work. Unemployment is often used as a measure of the health of the economy.

The Role of Technology in Thana–Capitalism

1

University of Palermo, Buenos Aires, Argentina

INTRODUCTION

We live in digital times, where events are covered and disseminated and consumed by a wider audience in seconds. This instantaneity paved the ways to the rise of a new digital culture where we can travel without even moving. The virtual reality has situated as the hallmark of a new 4.0 society (Warschauer & Matuchniak, 2010). To put the same in other terms, technology not only changed our current means of production but also the lifestyles as well as our habits, behaviours and social interaction with others (Gold 2012). The introduction of robots and virtual reality may very well erode the social ties since lay-citizens are certainly pressed to interact with an artificial “Other”. Doubtless, this is the end of hospitality as we know it (Korstanje 2017). In a seminal text, Jacques Ellul exerts a radical critique on “the technological society” shedding light on the negative effects of autocracy which are imposed by the logic of instrumentalism proper of the capitalist system. The legitimacy of the ruling elite is enhanced while the workforce passively accept the notion of efficacy as a form of genuine development. This creates a climate of extreme competence where only there is one winner and the winner of course takes it all. Ellul alerts that someday, humankind will be strictly controlled by Machines which move per their own ends. These automat robots are the direct result of an excess of rationality. He even toys with the belief that technology was conducive to the culture of capitalism in which case the logic of instrumentality mediates between citizens and their respective institutions (Ellul, 1964). Scholars are divided respecting to the role played by digital technology in the liberal world of consumers. Notably influenced by the legacy of Max Weber, Ellul was a pioneer in warning the grim future of humanity which may be subordinated to the exploitation of the liberal market. However, other voices like Guy Sorman (2008) claim that the forces of progress activate conservative counter-reactions that are oriented to prevent a more egalitarian society. Detractors of technology and its progress only are limited to tell part of the truth, which means the aftermaths of new techniques in the fields of the economy but ignoring those achievements promoted by technology as the expansion of life expectative or the improvements in healthcare overt recent years. As Korstanje and Skoll put it, neither good nor bad technology depends on the use people did. Concerned by the paradoxes of Chernobyl, modernity showed that technology enrooted in a world of complexities and uncertainty would be as “a runaway train” very hard to control. The paradox was that the same instrument will make of our life a safer place to dwell become in a global threat that very well jeopardizes our existence on this planet (Korstanje & Skoll 2014). Here some questions arise: what is the role of Technology in our modern World, is technology a mechanism of control or censorship in democratic societies? in what way?

Although technology facilitated plenty of liberties and rights for humankind over the recent centuries, which is protected by the contours of democratic institutions, no less true is that democracies still exert censorship over those voices which may place the system in jeopardy. In Medieval Times, writers or

DOI: 10.4018/978-1-7998-3473-1.ch015

thinkers whose texts were critical to the established status quo –i.e the King or the Catholic Church- were jailed, tortured and condemned to death. The violence was culturally and legally legitimated not only by the law but also by the power emanating from the divinity of the King. This seems to be the figure of Leviathan brilliantly described by Hobbes in his texts. The publication and resulting dissemination of books was limited to those voices strictly conducive to the interest of the King. Likewise, the idea of power associated to the capacity of the Monarch to instil terror in the community. Rather, in postmodern times, censorship is preferably achieved by the editorial over-production without limits and no matter whom or under what theme the writer focuses on. While we typeset –in Google- the name Karl Marx or Max Weber, thousands of entries appear. From the right to the left-wing, much has been written about classic authors. Since our mind is limited in the understanding, we would read only a small portion of all deployed works and publications. While in the medieval times the books are destroyed and thrown to the fire, in the postmodern days, books are systematically over-printed. In the capitalist ethos where liberty plays a vital role, consumers re-channel their whims and desires into standardized forms of behaviour. The overproduction leads to people not to understand the real causes of the events. For those lay-readers who are not familiar with the fields of sociology, it is very hard –if not impossible- to understand the rise and evolution of modernity. In fact, some may launch to read ten or twenty books but they will not understand what they read. In the post-modern days, hence, censorship is strictly entwined to the material forces of production, as well as affordable technology which is used to stimulate the consumerist culture. Based on the notion of liberty (or democracy) as the mainstream cultural value, capitalism overproduces information as an efficient instrument towards misunderstanding. Conducive to mass-consumption, freedom and democracy delineate the contours of societal order making the produced commodities affordable to consumers, but in so doing opens the doors for an atmosphere of conflict and discontent as never before. It is important not to lose the sight of the fact that this moot-point was brilliantly remarked by Ulrich Beck in his book *Risk Society towards a new modernity*. Beck critically debates to what an extent the process of flexibility has recreated a new condition for postmodernity. The problem lies in the fact that the society Beck observed, just after the 9/11 as well as stock market crisis in 2008 does not exist anymore. We coin the term “Thana-capitalism” to describe this new emerging society, where the Other’s suffering (not risk) became the main commodity.

Although this point will be detailed in the next sections, let’s explain readers that the term Thana-Capitalism denotes a new stage of the capitalist system where death is the main commodity to be exchanged. Not only the modern tourists consume death visiting spaces of mass death or cities which were whipped by natural disasters, but also we consume death through videogames, media and movies (to name only a few) (Korstanje 2016). The society of risk, as it was imagined by U. Beck, sets the pace to Thana-capitalism. In this emergent facet, not only technology played a vital role in subordinating social practice to gazing but also paved the ways for the needs of captivating the suffering of others. In times of Thana-capitalism, risk sets the pace to death as a mediator between citizens and their institutions. We mean to Thana, as a derived term from Thanatos (Greek) from Death. In the days of Thana Capitalism, global audiences gaze spectacles which are based on news, the content of disasters, mass-death or trauma. Citizens who are prone to gaze others’ death enthrall their own status as a part of privileged-class.

Theoretical Background

Over the decades, common questions asked on the evolution of science in Occident. Three different academic waves explored the interconnection of technology in the maturation of science. Econometrics, which initiate the first family of studies, signalled to mathematical algorithms to produce top-down

knowledge. Everything which cannot be visually tested was systematically rejected as a source of genuine knowledge. Human habits, not number were the key factors that distinguished these emerging disciplines from the economy. If classic science was prone to the premise of objectivity between observer and observed, sociology and anthropology gradually instilled a hermeneutics dialectics of knowledge which based on individual experience gave innovative outcomes (Cuevas 2005). Though this premise was already-evinced by young Marx, since the means of production mould the ideology for the society to understand the environment, it is tempting to confirm that technologies are subsumed under a historical dialectic imposed externally by an elite. This suggests that things are used to accomplish broader goals, but the underlying meaning for what we use these different objects is externally and culturally imposed by a privileged class (Marx, 1975; 1967; Marx & Engels, 1983). This raises a more than the interesting question, is technology a platform to alienation?

For H. Marcuse, the alienatory nature of technology rested on its capacity to alter the cultural background of society, which legitimized the asymmetries of classes (Marcuse 1991). Capitalism has imposed an “economy of desire” which absorbs the wages of work-force (Korstanje 2015). In this respect, David Harvey (1989) argues that modern means of production blurred the borders between space and time, accelerating the gift-exchange process. The oil embargo after 1972 produced a serious crisis to West which decentralized the economic system to the extent, that the concept of reality as it was envisaged by Enlightenment set the pace to multi-layered view of reality (Harvey 1989). In this context, French philosophy pivoted a radical criticism against the role played by technology and science in this ever-increasing process. From Weber and Sombart’s days, there was no other critical thinker as Jean Baudrillard that attacked the epistemological core of capitalism. For Baudrillard, capitalism has successfully expanded in view of the alternations of the epistemological viewpoint in what reality means. The visual technology in these times has not only altered the perceptions of citizens accelerating the intersection of time and space but the proliferation of textuality. In sharp contrast to other ages, modernity is based on the rise of computers where the meaning of publicity associates to the electronic World. To understand this better, he cites the example of Precogs, in *Minority Report* film, anticipate to the crime before it is committed. This reminds that the visual appearance of events does not imply they are happening in present; as these crimes were forecasted by Precogs in a future that modified the present or potential criminal, now pseudo-events are virtually shaping our sensual realm (Baudrillard, 1986; 1995; 2001, 2002). As Virilio puts it, technology played a leading role not only blurring the borders between past and time but effacing the difference between reality and pseudo-reality. In consonance with Baudrillard, Virilio understands that modern science remains subordinated to the interests of the market, instead of searching in the true, to solve the problems of citizens. More interested in supporting the financial mega-corporations, science embraces the paradigms of simulation, which reflects complex algorithms to understand the future. One of the chief aims of science, adjoined to technology, is to prevent the risks that may place the capitalist system in jeopardy (Virilio 2010).

Virilio’s account is oriented to exploring the limitations of modern science which today are not concerned with understanding issues, but forecasting hazardous events in order for the current system of consumption not to be affected. Doubtless, it opens the doors for a more creative discussion to understand to what extent science and the society of risk are inextricably interlinked.

Knowledge in the Society of Risk

The idea of a society of risk was coined by German Sociologist Ulrich Beck in observance of the role of nuclear technology in Chernobyl, Ukraine. This sudden disaster not only shocked public opinion

worldwide but also evinced the vices and limitations of experts in the manner technology are manipulated. Those instruments which originally would be featured for the benefits of humankind now result in global risks that put society upside down. In this vein, Beck adheres to the thesis that the presence of risk makes societies more egalitarian since all classes are united by the same problems. Paradoxically, this accident created a radical shift in how knowledge is produced and disseminated to lay-people. With the advent of the society of risks, consumption replaced ethics in the line with the fact that hope for full employment sets the pace to insecurity and fear. While lay-people advanced in their knowledge of the world, risks appealed to a process of “reflexibility” where the top-down authority of experts was placed under the scrutiny (Beck, 2002; 2009; 2015).

Following this ground-breaking contribution, Anthony Giddens goes on the open points unexplored in Beck’s account. For Giddens, capitalism and industrialism are different projects which originally worked dissociated each other. Taking his cue from the “attachment theory”, Giddens understands that social ties are represented in the ontological security developed by individuals from their childhoods. At the time, the emerging force of tradition is eroded by post-modernity; the ontological security of citizens will be seriously damaged. Trust serves as a “protective cocoon” in order for people to face the daily threats produced by the system. Without the blessing of trust, lay-citizens are more frightening of the future and will look shelter in technology. The process of reflexivity engendered more horizontal circuits of authority, and of course, the system of experts is confronted with the knowledge accessed by lay-people. To wit, the legitimacy of experts in the fields of medicine, to set an example, will depend on the credibility the professional instil in patients. In this stage, trust plays a crucial role configuring the social basis of a society that enthralled global risks as the mediators between citizens and their institutions (Giddens & Pierson, 1998; Giddens 1991, 1999). In consonance with Virilio, Giddens advises that in a near future, knowledge will be regularized by means of reflexivity in a way that will lead science to be prone to discover elements that help to forecast risks instead of studying facts. At a first look, what would be more than interesting to discuss is to what extent, in post-capitalist societies, the use of digital-technology produces more efficient censorship.

In regards to the dichotomy of Surveillance and censorship, a must-read book is *Liquid Surveillance*, authored by D. Lyon & Z Bauman (2013). Both agree though 9/11 has not created the current state of hyper-surveillance in modern capitalist societies, no less true is that this traumatic event accelerated its condition of reproduction. The already existent technologies are posed not only to make for public spaces, or households a safer place, but also to remind the importance of those persons who can pay for private security or closed-circuits of satellite control. This book suggests two significant ideas. First and foremost, the state is unable to protect its citizens because the power was conferred to trade. The modern nation-state is obliged to give solutions for problems created elsewhere. This engendered a sense of anomie, by which the citizens feel vulnerable. Secondly, the introduction of surveillance technology makes an unsafe world. The quest of order that characterizes human existence is determined by the needs of change. The paradox lies in everything that we do, is to create a sense of stability we never will reach before death. If the society of risk imagined by Beck considered the risk as a result of the action, liquid surveillance goes in another direction.

As this argument is given, Rebecca Fiske reviews the intersection of the state of exception with the law-making process, a strand ignited by Schmitt and recently continued by Agamben. Fiske starts from the premise that any law derives from the authority of Gods, and remain affordable for humans in case of emergency. The paradox with this doctrine is that while the notion of exemption supposes breaking the law, sovereign serves as a symbolic gatekeeper. While this applies very well for tribal societies, in industrial organizations where divinity exerts a moderate influence, the sense of exemption prevails.

Fiske acknowledges that after 9/11 US committed some human right violations, in the name of security and well-being. While emergencies allow the delegation of further powers to the executive branch, the judiciary often does not express any worry. This pattern would be very dangerous for democracy because it leads to dictatorship. After 9/11 the society of risk passed to a new stage where the spectacle of disasters would be the mainstream cultural value. Risk society mutated to Thana Capitalism, in the same way, the sense of protection set the pace to the needs of gazing others' death (Korstanje 2016). This will be fleshed out in the next lines.

The Rise of Thana-Capitalism

To some extent, not only Giddens but also Beck took the wrong side of the road in their analysis of capitalism. There is nothing at the end of class-society in postmodernity. Neither classes have disappeared, nor are citizens living in a more egalitarian society. In the society of risk, some groups make the decisions that generate those risks other more vulnerable groups will face. Given this condition, those classes which monopolize the financial resources to mitigate risks are situated at the top of society, while lower classes are condemned to experience the catastrophes triggered by decisions that are made in external circles. Lower-classes are far from controlling risks in a Thana-Capitalism, they are subject to witness their effects alone.

Throughout the Medieval Times, the access to knowledge was restricted to few hands. Without "The Printer", which was invented by Johannes Gutenberg's, the produced information was monopolized by the Catholic Church. Those agents, who defied the status quo, were coactively repressed and condemned to death. This was an oft-used tactic of censorship that instilled panic in the population. Violence and death were everywhere and a peasant has an expectative of life of almost 30 years. However, the invention of the Printer changed everything, enhancing the accessibility to books to lay people. The pressure and sense of control orchestrated by the Prince set the pace to subtler forms widely based on alienation and standardization. As Marshal McLuhan puts it, printing press accelerated a real revolution in European thinking to the extent to produce a mega-system of global communication (Global Village) where the efficacy of the system was given by its ability to gather information. However, in this universe, this information was not equated to a critical thinking. Hence, the expanse of high-tech has not made from this society a better place, they were oriented to create "false identities" which are imposed and individually negotiated by the agents. High-tech enrooted in the culture to produce habits in users. In one direction, the creation of movable types was a turning point to reproduce thousands of books, which led towards a society of information, whereas unfortunately it was created a "tyranny of visual culture" cemented a standardized-culture (McLuhan, 2011).

In our current days, the society of risks examined by Giddens and Beck has gone forever, or at least it has mutated into a new form: *Thana-Capitalism*. Risk-Capitalism essentially was associated with bio politics and the needs of life, Thana Capitalism centres on the opposite, death. In sharp contrast to Medieval Age, in Thana-Capitalism people have a high expectancy of life, but live frightened by the possibility of death. Consumers are fascinated to witness spectacles where others are affected, killed or tortured. Death has become the main cultural value in this new society, where 24 hours per day, TV and Journalism only transmit news linked to death. News that oscillates between disasters, terrorist attacks or local crimes daily captivates an audience more interested to feel more special than consternated for a run-a-way World. In many newscasts, it appears a message that says "images may hurt your sensibility", or Warning, videos and images not for children". At a closer look, even if the audience in the developed

societies is bombarded to catastrophic news with the end of keeping the society in an on-going state of emergency, no less true is that death has become in a form of entertainment.

As Phillipe Aries eloquently observed, the expectancy of life was notably expanded but this does not resonate the quality of life. For the medieval peasant, the act of dying was normal and death was surely everywhere. Over the years, humankind has controlled death while making it more savage and wild. Today we are afraid of death as never before. Our modern attempts to domesticate death has liberated a much deeper uncertainty (gap) which is filled by the Media (Aries 1975)

To wit, five indicators are of paramount importance to observe the end of the Risk-Capitalism and the rise of Thana-capitalism.

Differences between Risk and Thana-Capitalism

Risk-Capitalism Thana-Capitalism	Politics Decentralized Chaotic	Economy Segments Total Competence
Production Consumption Survival of the fittest	Main Value Risk Death	Event Oil Embargo (1972) 11 September of 2001
Reaction Risk Management Victimization	Pressure Group OMG Victims	Censorship. Fear Over-production of information

We mean OMG as Object Management Group. Further, Table 1 shows the differences between Risk and Thana-Capitalism. The society drawn by Giddens and Beck corresponds with Risk-Capitalism. The organization of this system was centred on a decentralized mean of production where globalization attracted heavy investment in any part of the world. The maximization of profits and the reduction in costs was the main goal of risk-society. Even under-developed countries were more attractive for investors because the lower work-force costs respecting to central economies. As Taylor Gooby (2004) noted, the same technology that expanded the expectancy of life and enhanced the quality of life of elderly class produced a serious imbalance in the social security costs because active workforce should absorb an ever-growing demand of retirees that threatened the balance of the system. Secondly, the adoption of new technology to efficiently maximize profits of capital-owners reduced the supply of jobs for a prioritized blue-collar class. All these events conjoined to the oil Embargo caused by the Arab Israeli war produced a serious glitch in the good fare state that initiated a new version of capitalism, more based on fear as a dissuasive element of control. In *Governing through Crime*, J. Simon evinced how ruling elite appealed to create “an evil-doer” in order for the workforce to accept economic policies otherwise would be widely rejected (Simon 2007). Neoliberalism alluded to the sensationalism and fear disasters wake up in a society in order to ensure a logic of exploitation over workforce (Klein 2007). Since the main cultural value in the society is a risk, the reaction of citizens corresponds with the management of risk, which is associated with the needs of protection. As this backdrop, citizens go to the private market in the absence of nation-state, whereby the paying of a quota of capital they get a temporal sense of security. By means of the buying insurances for protection, the society of risk still produces new commodities to be exchanged in a global market. The tactic of discipline or censorship over citizens depends on the degree of the fear elite can produce in society. Frightened by the presence of global fears that can end with life as we know, citizens are sensitive to the market to pay for the security the state does not grant. However, one thing is using technology to predict disasters, and others go to the high-tech to produce a “theatralization of disasters”. In the second case, death is enthralled as an attractive factor of western culture in the contemporary World.

During the risk society, people lived afraid the disaster will be next to take place. The specialized literature suggests that risks are not disasters. Risk is a potential danger which can occur or not. Therefore, the society of risk was oriented to a future. Understanding the dangers hidden in the future will be an efficient attempt to protect society. Thana-capitalism, rather, promotes disasters in order to entertain a global audience dubbed as “death-seekers”. Seeing how others die serves as a symbolic platform for the watcher to feel how outstanding he or she is. This is the reason why terrorism or news related to terrorist attacks are covered instantly by the media. We are fascinated by the state of disaster produced by risk society. Technology not only has disciplined the real external or internal threats but it has commoditized lower classes’ suffering as a new type of cultural entertainment (Korstanje 2016).

Doubtless, 9/11 was a founding event for the rise of Thana Capitalism. From this moment on, not only Western audience acknowledged that the world was an unsafe place to be, but they witnessed how their high-tech and transport applications can be used as weapons to the cultural core of the world. In this new era, coaction and violence were futile and censorship was politically manipulated to cause misunderstanding in lay-people. The term Thana-Capitalism stems from the word Thanaptosis which was originally coined by poet William C Bryant to symbolize the cycle of life and death. We live in order for others to die, and we will die so that others can live. Furthermore, Thanatos (Θάνατος) comes the name given to a demon who represented the personification of “death”. In this new stage, capitalism signalled to a much complex system of production which exploited the symbolism of death. Since the conditions of production passed from a decentralized model to a chaotic one, where all agents enter in the competence with others for surviving, the doctrine of Thana-capitalism follows doctrines of social Darwinism where protection set the pace to the Survival of the strongest. Sometimes, holiday-making and vacations give some hints on how societies are changing. Our parents went to beaches or relaxing sites to spend their days while now tourists are excited to visit spaces of disaster as Chernobyl, Katrina in New Orleans or even the ground zero in New York. Sociologically, if holidays-makers have developed an Apollonian sense of beautiness, now they are in quest of spaces of mass-death and suffering to revitalize the psychological frustrations they daily experience in their respective societies. Death has gained traction in thana-capitalism, captivating the admiration and becoming in a real tourist-attraction for many international segments (Bloom 2000; Stone & Sharpley 2008; White & Frew 2013). Knowing further on what purposes people travel exhibits a valid way of understanding of what values society is organized (Korstanje 2015). Is dark tourism a sign of egoism or a real attempt to understanding Death?

Several decades back, George H Mead, one of the fathers of symbolic interactionism, questioned why paradoxically many people are prone to read or listen of bad news presented by journalism, at the time they show preference by these types of news. What is our fascination for other’s suffering? He assertively concludes that the self is configured by its interaction with others. This social dialectic alludes to anticipation and interpretation as two pillars of communication-process. The self feels happiness by other’s suffering because it represents a rite necessary to avoid or think in own pain. Starting from the premise the self is morally obliged to assist the other to reinforce its sentiment of superiority, Mead adds, this is the ethical nature of the social relationship (Mead, 2009). The same remarks may apply for thana-capitalism.

Undoubtedly, the myth of Noah sounds one of the main stories of the Bible which was commoditized by the cinema industry. Such a myth not only explains but also legitimizes the material asymmetries produced by Thana-Capitalism. Let’s remind readers that this God annoyed by the corruption of human beings, mandated to Noah to construct an ark. His divine mission consisted of gathering a pair by species to achieve the preservation of natural life. The world destroyed by a great flood will be reconstructed by the species protected by Noah. At a first glance, as the myth was ethically formulated, a formal message

is based on the importance of nature and the problem of sin, corruption. But unconsciously, it poses the dilemma of competition where Thana-capitalism is centred. At any tournament or game, there can be only one winner. Not only the creation but also Noah is the witness of other's death, other's mass-death. The curiosity and fascination for death come from this founding myth. The fact is that it can be found in Reality shows as the big brother, a game widely studied by sociologists and detractors of visual technology rests on this principle. The main message of this game is only one participant is the chosen one to win. The doctrine of selective-oriented salvation, enrooted in Protestantism claims for (though from different angles) understanding death as a token of vulnerability, lack of purity. The question of whether people are happier when disaster takes place in other neighbourhoods, it is still unclear the intersection of disasters and social bondage (Korstanje 2015; 2016).

It is important not to lose the sight that shrines reminding spaces of disasters are dispositifs politically enrooted in the "spectacle of disaster", as discussed in the earlier sections, a term coined by Jean Baudrillard. By thematising on disasters the community accelerates its recovery understanding the lesson left by the nature. Humankind from its inception is aimed at disciplining not only the nature but death. Like disasters, death can suddenly take room in our life (without previous notice). As a result of this, survivors feel a much deeper anxiety which is placated by the elaboration of specific-contextualized rites. The notion of trauma does not relate to the pain, but to the possibility the tragic event repeats in a near future. In the context of total obliteration, survivors develop a narcissist character where they believe they have survived because their bravery, moral virtue and strength (outstanding and heroic traits). This type of reaction helps the community to recover to adversity while generating sentiments of nationalism, superiority or ethnocentrism when this narcissism goes beyond the normal conditions. The superiority of survivors, in this vein, depends on the other's misfortune. Unless this sentiment of narcissism to be regulated, it produces a clear rupture that affects social solidarity. Survivors feel they are super-heroes or special people touched by Gods, their mandates not only are sacred but also just. At this moment, this sentiment of superiority feeds back a much deeper stage of victimization where survivors feel that pain is the only mean to reach happiness. Quite aside from this, their losses make them special for others who have not faced the same situation. In Thana-capitalism the Other's suffering reinforces a self-heroic aura of superiority where the viewer feels special –at least for some minutes-. Thana-capitalism in sync with existent visual technology, not only exploits these types of climates but also obscures the causality of events. French ethnologist, Marc Augé acknowledged that the mass-media portrays tragic events blurring the connection between causes and consequences. News or stories focus on the effects instead on a clear diagnosis of reasons behind. As a result of this disasters' are continuously repeated once and once again (Augé, 2002). Not surprisingly, mass-media disseminates on a daily basis, news containing stories of victims to reinforce the above-described sentiment of Narcissism.

CONCLUSION

In the days of *Thana-capitalism*, death is the main commodity which is produced and disseminated by the media worldwide. As in dark tourism practices, people are interested to gaze the Other's suffering but in fact, far from being closer to others, it reinforces their happiness not to be touched by death. Since thana-capitalism is based on a social Darwinism where all are struggling against all to survive, others' death endorses an exclusive sign of supremacy for those who are still alive. Metaphorically speaking, life is understood as a thrilling race where only a few selected participants win. In reality shows like Big Brother, or Films like Hunger Games, there is only one winner. The competence of all against all

is promoted by a cynic leader who looms from the darkness. This suggests that participants of these games not only are unfamiliar with their real probabilities to fail, in view the fact that they are moved by their own egocentrism but they are unable to cooperate with others to defeat the ruling elite. Is this a continuation of Social Darwinism?

It is safe to say that without social Darwinism, Thana-capitalism would never exist. As discussed throughout this chapter, at time of researching for some issues the records visible in the media prevent a coherent understanding of social issues, this multiplication of information paved the ways for a paradoxical situation where only a few hands monopolize what can be or not written. If in medieval times, the censorship was oriented to violence now it is related to liberty and the scattered information that leads to misinformation. This is only possible in a new era, dubbed as “Thana-Capitalism”. Nowadays, technology offers a fertile ground to visualize the suffering of “Others” connecting our self to death, whereas stimulating the over-production of information. With the benefits of hindsight, this chapter holds the thesis that death, censorship and technology are inextricably intertwined. In medieval times where death was a very common thing in day-to-day life, produced-information was reduced to limited circles. The lower technical condition of production was prone to use violence to exercise censorship to the peripheral voices.

Lines for Future Research

The argument held here may find much criticism in liberal thinkers, who argues that capitalism helped not only to crystalize democracy but making of this world a less violent realm (Pinker, 2011). However, the problem of capitalism rests on the belief that few deserve much, while the rest are on the ruin. Almost 2% of the global population concentrates 90% of the produced wealth. In a recent book, Maximiliano Korstanje (2015) alarmed that this postmodern world can be compared to the film Hunger Games, or the reality shows Big Brother. In both settings, participants are dominant of their conciseness because they remain unfamiliar with the real probabilities to fail. These competencies, like liberal market, are based on the premise of social Darwinism that claims for “the survival of strongest”, which means that the glory of only one equals to the failure of the whole rest. Participants not only over-valorise their own skills but are confident of their strongholds. The stimulation of competition in the labour market, emulated by the entertainment industry, resulted in two interesting dynamics. The vulnerability of rank-and-file workers associated with the decline of the well-fare state facilitated the capital-owners to increase their profits and wealth, while the risk was adopted as a new value for modern workers. After all, the spectacle of disasters confers to workers the idea they are co-manager of their own fate. As things come from worse to worst, workers not only are responsible by decisions others make but in Thana-Capitalism, elite eludes its responsibilities to fail in paving the conditions for fairer wealth distribution.

On another hand, capital flourishes in a climate of liberty to move across the world. The doctrine of liberty (democracy) stimulates in workers the needs of consuming, in terms of Donohue, a type of freedom from “want”. The change from a society of producers to consumers took hit after the 40s decade. Ideologically, Americans have felt “superior” to other nations because they are enthralled as the main democratic and prosperous society; although more egalitarian at the surface, American citizens are subject to more work and consumption but less leisure. This happens because, in a pro-consumer society, workers are bombarded with emulation and advertising creating the needs to buy. This not only jeopardized their real liberty to choose but affects seriously to democracy. Detractors of capitalism, who pushed their focus on the arbitrariness of producers, were involuntarily responsible or conducive to the formation of a global society of consumers. Those denunciations on an economy that protect the interests

of producers as well as the needs to adopt consumption to break the material asymmetries among classes, were two guiding concepts to the formation of a globalized version of capitalism, which paradoxically was prone to mass-consumption but producing serious vulnerabilities (Donohue 2003). Despite the hot-debate ignited in this chapter, we feel the much deeper investigation is necessary in order to provide an all-encompassing model to understand these times where death seems to be exchangeable in every sphere of society. Precisely, in Thana-Capitalism digital information acts as a mechanism of censorship successfully orchestrated by over-abundance.

KEY TERMS AND DEFINITIONS

Censorship: It means the suppression of free speech rights or any right to express own ideas.

Digital Surveillance: The use of digital technology to control others, citizens, and the life of a nation.

Globalization: It refers to a cultural project of integration of economies and networks which leads to multiculturalism and interchange of worldviews.

Risk Society: It is the ways a society reacts against the rise of risks. Risk society alludes to the needs of forecasting future to prevent potential threats that may affects societal order.

Thana-Capitalism: This represents a new term just coined in this manuscript where death situates as the main commodity of good exchange process and current economic systems. Thana capitalism replaced risk society after 9/11.

INTRODUCTION

Organizations continually need to develop new policies and undertake policy evaluations in a variety of contexts with a view of determining their feasibility and the possibility of adopting them. Such policies may be internal ones relating to the procedural structures or workflows within the company, or ones that relate to its management or operational strategies, e.g. should the company use a particular advertising channel. A key consideration in the course of policy evaluation is the underlying environment within which the policy learning and evaluation is performed. It is often the case that the dynamics of the environment is of such a level of complexity that the result of each evaluation tends to exhibit significant variability which is governed by a variety of factors of a non-deterministic nature.

In order to systematically determine the feasibility or optimality of a new policy or strategy, it is necessary to observe its performance and monitor the outcomes of repeated trials. Repetitive sequential trials are important and necessary in order to ensure reliability and ongoing effectiveness particularly in an environment which is subject to chance influence and where complete information on all the underlying factors are not available. Such trials need to be undertaken in a methodic manner and they need not be limited to:

1. Evaluations carried out by a single organization; i.e. such evaluations can be undertaken by different stakeholders representing the interests of different organizations
2. Evaluations carried out prior to adoption or acceptance; i.e. such evaluations can continue well beyond the acceptance or delivery phase.

In general, such evaluations may be undertaken with varying degrees of stringency – more stringent criteria should be adopted for safety critical operations, while less stringent ones may be used for non-mission critical policies.

We shall make use of an example particularly relevant to current concerns to illustrate some of these points. Recently there have been heightened global concerns regarding aviation safety, as multiple fatal crashes have occurred across different parts of the world relating to a particular model of aircraft, which took place within the space of only a few months. To be concrete, we shall use Model X to denote the particular model of the aircraft, where the policy in question is to adopt Model X for service. At the

DOI: 10.4018/978-1-7998-3473-1.ch016

very beginning of the process, it starts with a learning stage – one needs to learn whether Model X is sufficiently safe to be in service. Such learning is done by carrying out repeated flights (trials) of the aircraft, with each trial labeled a success or a failure. In the context of reinforcement learning, a success corresponds to a reward, while a failure corresponds to a punishment. Subsequent to the initial stage, in a strict sense learning still continues and never stops as ongoing data are gathered about the safety of Model X. There are three types of organizations involved in the evaluation process, and these include:

1. The manufacturer of Model X
2. The aviation safety certification authority
3. The many client companies that use Model X for its daily operations.

Each flight of Model X may be regarded as an evaluation trial, and hopefully each flight would be uneventful and be labeled as success. Unfortunately, such were not the case for Model X. While the first type of organization concluded from their own pre-delivery trials resulted in overall success and acceptability, such success did not continue to hold subsequent to aircraft delivery. After delivery took place, trials did not stop but continued to be carried out by the client organizations. While these trials were still labeled as success at the very beginning, the policy was put in doubt due to some disastrous outcomes, which resulted in the termination of the policy (i.e. ending the adoption of the Model X for service) and the global grounding of the aircraft.

In most practical situations, the cost of carrying out such learning trials can be significant. We thus see in our example that through repeated trials resulting in outcomes of either reward or punishment, one establishes the feasibility of the new policy and completes the learning phase. Sometimes subsequent to the learning phase, the new policy, if learned successfully (i.e. when the rewards to punishments ratio is sufficiently high), may be adopted from that point onwards without it being questioned or evaluated afterwards. In some situations, one tends to assume that the learning is primarily done during the pre-adoption phase. In most situations, however, even after the policy is adopted, ongoing validation and monitoring is still carried out and this is especially necessary for safety-critical and mission-critical operations, as illustrated in this aviation example. If in the course of ongoing monitoring, there is an overwhelming number of punishments observed, then the adoption of the policy may be called into question, and termination of the policy may be necessary.

In this Chapter, we shall explain how reinforcement learning can be leveraged for organizational policy evaluation, and describe how to deploy a Monte Carlo approach to learn and estimate the underlying structure of the environment by making use of the observations gathered in the course of the evaluation process. We shall provide practical rules for such learning reinforcement scenarios where rewards and punishments for both the pre-adoption phase as well as the post-adoption phase are received. To be concrete, we shall continue to use a scenario of aviation safety, as we believe this scenario is sufficiently general and of particular relevance and currency to present day concerns. Despite this, we wish to point out that many other everyday learning situations are similar to this; examples include trialing a new machine translation algorithm, learning the effectiveness of a new advertising channel, and route discovery in self-drive vehicles.

BACKGROUND

Some definitions of terms or concepts will be useful before we proceed further. These will be used in the rest of this Chapter and are given as follows.

1. **Intelligent Agent:** an intelligent agent, usually equipped with sensors and actuators, is an autonomous entity directing its action towards achieving its goals within a given operating environment
2. **Monte Carlo Methods:** Statistical estimation methods that involve the use of a significant random component
3. **Multi-agent:** a multi-agent framework is one that multiple intelligent agents operate and interact, with the action of one agent affecting the actions and decisions of other agents
4. **Reinforcement Learning:** reinforcement learning is concerned with how agents should act within an environment where rewards and punishments are handed out for their actions, with the aim of maximizing reward and minimizing punishment
5. **Stopping Rule:** A stopping rule in a reinforcement learning situation is a rule that determines if an agent should terminate a learning episode as a result of the number of rewards or punishments received
6. **Supervised Learning:** in supervised learning, an agent is given labelled input/output pairs with the aim of the agent correctly associating the input with the output after undergoing some training
7. **Unsupervised Learning:** in unsupervised learning, an agent is to find previously unknown patterns in data without pre-existing labels.

An autonomous agent in reinforcement learning learns through the interaction with the environment to maximize its rewards, while minimizing or avoiding punishments. In most practical situations, the underlying environment is non-stationary and noisy (Ziebert *et. al.* 2008, Arulkumarn *et. al.* 2017, Wu *et. al.* 2016), and the next state results from taking the same policy may not result in the same outcome every time but appears to be stochastic (Ipek *et. al.* 2008). In (Brafman *et. al.* 2002), Brafman and Tenenholtz introduces a model-based reinforcement learning algorithm R-Max to deal with stochastic games. Such stochastic elements can notably increase the complexity in multi-agent systems and multi-agent tasks, where agents learn to cooperate and compete simultaneously (Panait *et. al.* 2005, Tampuu *et. al.* 2017). As other agents adapt and actively adjust their policies, the best policy for each agent would evolve dynamically, giving rise to non-stationarity (Busoniu *et. al.* 2008, Albrecht *et. al.* 2018). In these studies, the cost of a trial to receive either a reward or punishment can be seen to be significant, and ideally, one would like to arrive at the correct conclusion by incurring minimum cost. In reinforcement learning algorithms, one is always in the hope to rapidly converge to an optimal policy with least volumes of data, calculations, learning iterations, and minimal degree of complexity (Moore *et. al.* 1993). To do so, one should explicitly define the stopping rules for specifying the conditions under which learning should terminate and a conclusion drawn as to whether the learning has been successful or not based on the observations so far.

Establishing stopping rules, is an active research topic in reinforcement learning, which is closely linked to the problems of optimal policies and policy convergence (Wei *et. al.* 2017). Conventional approaches mainly aim for relatively small-scale problems with finite states and actions. The stopping rules involved are well-defined for each category of algorithms, such as utilizing Bellman Equation in *Q*-learning (Watkins *et. al.* 2008). To deal with continuous action spaces or state spaces, new algorithms, such as the Cacla algorithm (Hasselt *et. al.* 2009) and CMA-ES algorithm (Hansen *et. al.* 2003) are

developed with specific stopping rules. Some stopping rules for stochastic reinforcement learning under different assumptions have been proposed and studied in (Panda *et. al.* 2018, Hong *et. al.* 2015). Still, most studies on stopping rules are procedure-oriented and do not have a unified measurement where comparison may be facilitated.

In our study here, in addition to learning from the observations in the pre-adoption and post-adoption phases, we also focus on the stopping criteria, so that what has been observed and learned can form the basis of policy decision making.

A DECISION FRAMEWORK FOR POLICY EVALUATION

Learning Criteria and Basic Formulas

Here, we are dealing with a learning sequence each of which either incurs a positive reward or negative reward (i.e. punishment). We are interested in determining whether the sequential observations indicate overall success or failure. Evidently, if the number of positive rewards gathered is much greater than the number of negative rewards, then the conclusion drawn from the learning episode should be success, while if the opposite is true, then the corresponding conclusion should be failure. Consequently, through such learning sequences, the policy may be gradually reinforced and built up.

In order to proceed with the quantitative analysis, we first let p and q (with $p + q = 1$) denote the probabilities of receiving a positive reward or negative reward respectively for a given observation. Later on, in keeping with the Monte Carlo approach, we shall derive estimates for p and q which capture the stochastic structure of the learning environment. For example, if $p > q$, then clearly the final conclusion should be learning success. An error often committed is that when the first few observations are all negative, one would terminate prematurely and return a verdict of failure for the learning episode. Let us consider the stopping rule:

Rule A: *An agent stops a learning episode upon observing r positive rewards. The learning episode can be concluded as a success or a failure according to whether the number of positive rewards is sufficiently greater than the number of negative rewards.*

This is in fact a family of rules since there are two parameters that need to be specified. The first is r , and the second is related to “sufficiently greater”, both of which need to be indicated in a more detailed and quantitative manner.

Consider the probabilistic model of *Rule A*. Let the random variable T be the number of observations preceding the first positive reward; i.e. T may be regarded as the waiting time to the first positive reward, measured in number of observations. Since after the occurrence of the first reward, the process probabilistically repeats itself again, so that we shall calculate the waiting time W_r of the r th positive reward. In Appendix A, it is shown that the mean and variance of W_r are given by

$$E[W_r] = \frac{rq}{p}, \quad (1)$$

$$\text{Var}[W_r] = \frac{rq}{p^2}. \quad (2)$$

Furthermore, the probabilities $\Pr[W_r = k]$ may also be obtained as,

$$\Pr[W_r = k] = \binom{-r}{k} p^r (-q)^k, k = 0, 1, 2, 3, \dots \quad (3)$$

Since W_r is the sum of independent identically distributed random variables, when r is appreciable, it may be approximated by the normal variate by virtue of the Central Limit Theorem (Feller, 2008) so that

$$W_r \sim N\left(\frac{rq}{p}, \frac{rq}{p^2}\right), \quad (4)$$

where $N(\mu, \sigma^2)$ denotes the normal distribution with mean μ and variance σ^2 . Thus, the probability $\Pr[W_r > b]$ may be approximated by

$$\Pr[W_r > b] = \int_{\frac{bp-rq}{\sqrt{rq}}}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} dt = 1 - \Phi\left(\frac{bp-rq}{\sqrt{rq}}\right), \quad (5)$$

where Φ is the standard normal distribution.

B. Monte Carlo Estimation

Here, we shall estimate p from the trial observations. Let ρ signify the ratio of the average number of negative rewards to the number of positive rewards, which can be obtained from (1)

$$\rho(p) = \frac{E[W_r]}{r} = \frac{1-p}{p}. \quad (6)$$

It is interesting to note that the rewards ratio is linearly correlated to the probability ratio of negative rewards to positive rewards q/p . For successful learning, a necessary condition for an optimal policy is to have the number of negative rewards strictly less than the number of positive rewards or $\rho < 1$. From (6), this is equivalent to $q < p$, implying $p > 1/2$.

In our Monte Carlo estimation problem, we shall determine the inherent stochastic structure of the environment by estimating p from the actual observed rewards ratio W/r , where W is the sample mean of W_r . From (6), solving for p , we can form the estimate

$$\hat{p} = \frac{1}{1 + W/r},$$

and we see that $\hat{p} > 1/2$ if $W/r < 1$.

Generally, we wish to have a small value for ρ , so that the average number of negative rewards received is much less than the number of positive rewards, i.e. $q \ll p$. In Figure 1, the change of $\rho(p)$ is shown as p varies over the range (0,1), where ρ reaches unity at the point (0.5, 1). We see that as p tends to 0, the rewards ratio ρ tends to infinity. It intuitively suggests that if the probability of receiving a single positive reward is small, the number of negative rewards on average will be high. In order to have a small rewards ratio for successful learning, so as to maximize the relative number of positive rewards, p should be significantly greater than 1/2.

As mentioned above, the indication of “sufficiently greater” in *Rule A* requires quantification. Here, we pre-specify a particular fraction of negative rewards ρ^* (< 1), so that upon the completion of a learning episode, i.e. r positive rewards are observed, if the actual number of negative rewards W is such that $W/r < \rho^*$, the learning is concluded as successful; otherwise, it is regarded as a failure. Possible values of ρ^* may be 30%, 50% or 70%, depending how stringent is the learning correctness criterion. In any case, either type of error – i.e. wrongly concluding success or wrongly concluding failure – is unavoidable, as in standard statistical testing. In the case of $\rho^* = 100\%$, we have $W = r$, and it would be difficult to draw a definite conclusion concerning the learning outcome, and to be conservative, one would therefore conclude that the learning has been unsuccessful.

Probability of Exceeding Cost Bounds

The mean value, being a single statistic, is often not sufficient as it fails to fully reflect any statistical fluctuations. In many cases, as in the advertising example, the cost of observation is significant. Let c be the numerical representation of the cost associated with an observation. Having specified r , a minimum observation cost of rc must

therefore be incurred. What is uncertain is the number of negative rewards obtained, and ideally to achieve minimum cost, this number should be bounded. Supposing we would only sustain a maximum cost of bc for observing b negative rewards, we shall estimate the probability P_b that the learning cost for this component exceeding this bound. From (3) above, this is given by

$$P_b = 1 - \sum_{k=0}^b \Pr[W_r = k] = 1 - \sum_{k=0}^b \binom{-r}{k} p^r (-q)^k. \quad (7)$$

The computation associated with (7) is somewhat laborious. As indicated above, when the value of r is large, we can make use of the normal approximation (5).

A COMPETING MULTI-AGENT LEARNING FRAMEWORK

In *Rule A* above, the termination of a learning episode is triggered whenever a fixed number of positive rewards r is obtained, irrespective of the number of negative awards accumulated in the process of doing so. Sometimes, however, this may not be desirable, especially when an inordinate number of negative rewards have been accumulated, in which case, termination should take place earlier along with the conclusion of policy learning failure. Therefore, one is comparing the number of positive rewards gathered against the number of negative rewards, and the learning is concluded as success or failure according to which of these achieve the majority.

Figure 1. Changes of Rewards Ratio

More precisely, this may be viewed as a multi-agent game with two competing agents A and B , in which A is responsible for giving out the positive rewards, while B , the negative rewards. This framework is not unlike the game theoretic approach in statistical decision theory, where both the statistician and nature are regarded as players in the game of estimation, and also this may be regarded as a kind of stochastic game (Brafman *et. al.*, 2002). While we shall focus on the agents A and B , we note that there is a further agent, the learner, so that three agents exist in this situation. Here, when an observation results in a positive reward, then A would gain a score of one, while when an observation results in a negative reward, then B would gain a score of one. When either score first reaches a given threshold h , then this will trigger a termination and the learning episode is concluded as success or failure according to which agent attains the threshold score first. Therefore, we have the following stopping rule:

Rule B: A learning episode stops upon either agent, A or B , first reaching the threshold of h rewards. The learning episode can be concluded as a success or a failure according to which agent attains the threshold first.

Here, without loss of generality, we shall let $h = 2m+1$ be odd, where m is an integer, and similar to Section III, we let p and q , with $p + q = 1$, signify the probabilities of receiving a positive reward and negative reward respectively for a particular observation. In other words, for a given observation, agent A wins with probability p , while agent B wins with probability q . We shall call p the *winning propensity* of A , and q the *winning propensity* of B . We see that it is essentially the winning propensity that governs which agent will ultimately win the game in the long run. Appendix B derives the probability P_m that the learning is successful (i.e. agent A wins) according to *Rule B*, which is given by

$$P_m = \sum_{k=0}^{2m} \binom{4m-k}{2m} p^{2m+1} q^{2m-k}.$$

Table 1. Probabilities of Learning Success

m	p	q	P_m	m	p	q	P_m
1	0.5	0.5	0.5000	5	0.5	0.5	0.5000
	0.6	0.4	0.6826		0.6	0.4	0.8256
	0.7	0.3	0.8369		0.7	0.3	0.9736
	0.8	0.2	0.9421		0.8	0.2	0.9990
	0.9	0.1	0.9914		0.9	0.1	1.0000
2	0.5	0.5	0.5000	10	0.5	0.5	0.5000
	0.6	0.4	0.7334		0.6	0.4	0.9035
	0.7	0.3	0.9012		0.7	0.3	0.9964
	0.8	0.2	0.9804		0.8	0.2	1.0000
	0.9	0.1	0.9991		0.9	0.1	1.0000

Table I computes P_m for different values of p , q , and m . We see that, as expected, when $p = q = 1/2$, $P_m = 1/2$, since neither A nor B has any advantage over its opponent. As p increases, however, P_m will increase, reaching almost certainty as p increases beyond 0.8. If we regard p as a

measure of A 's winning ability per trial; then when $p \gg q$, most trials will be scored by A , so that winning the entire game (i.e. reaching h first) is almost a certainty, and this is especially so for higher values of h . It is interesting to see that when h or m is sufficiently high (e.g. $m=10$), a moderate advantage for A (e.g. $p = 0.6$) is enough to almost guarantee success. On the other hand, $1 - P_m$ gives the probability that agent B wins, where the measure of B 's winning probability per trial is given by q . For instance, when $q=0.4$, then B stands a chance of around 27% of winning the game when $m=2$, and a chance of winning of around 10% when $m=10$.

Returning to the Monte Carlo estimation problem, by observing P_m , i.e. by computing the observed proportion of time that agent A wins, it is possible to infer the underlying probability p . While unlike in Section III, where an explicit formula exists linking directly the observations to the estimate, such explicit relationship is not available here. Nevertheless, as can be observed from Table I, useful estimation bounds can be drawn to determine whether $p > 1/2$ or $p < 1/2$. We see that it is quite reasonable to estimate $\hat{p} > 1/2$ whenever $P_m > 1/2$, and this would seem sufficient for most practical purposes.

LEARNING SITUATIONS WITH CONTINUOUS SUCCESSES OBSERVED

In some situations, such as the routine introduction of a new product or service, one would tend to assume that the policy in question will never be revoked (i.e. withdrawal or recall of the product). In a business environment where nothing can be regarded as totally certain, there is a small but non-zero probability that the policy would fail no matter how many times that it has been validated by consumers. In such situations, an organization would still wish to know the probability of this happening, since a small probability amplified across a huge product range may result in an appreciable probability.

Let there be N evaluations so far, and these evaluations may include those carried out by the company offering the new product prior to putting it on the shelf, or evaluations carried out (implicitly) by consumers after they have purchased the product. Supposing the outcomes of all N evaluations resulted in

successes, then the probability f that the next evaluation (use) will result in a failure is given by (Feller, 2008)

$$f = 1 - \frac{N+1}{N+2}.$$

This is obtained from Laplace rule of succession, which estimates the probability that the sun will rise tomorrow, given it has always risen in the past. We note that from the above equation that the probability f tends to zero as N becomes large. However, if the number of products M is also large, then the probability of any one of them failing is

$$1 - (1 - f)^M.$$

which can be appreciable.

FUTURE RESEARCH DIRECTIONS

A useful assumption that we have adopted is that positive rewards and negative rewards occur independently. In future, it may be useful to relax this assumption and incorporate Markov chains into the analysis. Usually a single-step Markov chain should be sufficient, but for safety critical systems where a high degree of accuracy is required, then a multi-step Markov dependency will be necessary. It is likely, however, that the corresponding analysis and Monte Carlo estimation procedures will be considerably more computationally intensive.

Secondly, the rewards and punishment structure in this Chapter mainly follows the execution of a stochastic random walk process where each step of the walk is assumed to be of unit length. In future, more general random walk patterns may be used, where the step size may in turn be a random variable. This more general model should be more versatile and may be used to represent varying degrees of reinforcements and punishments which would subsume the present situation as a special case.

CONCLUSION

Since learning environments are often noisy and seldom static nor deterministic, by exploiting the random data collected in the course of the evaluation process, the use of Monte Carlo estimation methods is therefore able to provide useful estimates of the underlying environment. Indeed, if stochastic elements are absent, the same outcome will always occur, obviating the need for repeated observations. This Chapter focuses on policy learning and evaluation that occur in a wide variety of application contexts. We first consider a situation where the cumulative number of rewards is pre-specified and fixed, which constitute the criterion for stopping the learning episode. By observing the random positive to negative rewards ratio, a meaningful estimation of either learning success or failure may be arrived at. In most practical situations, the cost of observation can be significant, and this has been incorporated into our model, with the probabilities of exceeding the observation cost bounds also given.

We next consider a multi-agent framework where the handing out of positive and negative rewards are viewed as being performed by agents. Thus, the final learning outcome is determined by a kind of stochastic game with the associated agents competing against each other. The stopping criterion here is determined by when and how the game is won. For this scenario, the respective probabilities of learning success and relevant measures of interest are obtained. Here, winning achieved by the appropriate agent will result in the successful adoption of the policy, and a procedure for estimating the underlying stochastic environmental structure, as represented by the winning propensity, from the observed random agent winning frequencies is also employed.

In addition, we also consider situations for product evaluations where the policy success rate is high but the product range is large, and have also presented a simple formula for estimating the probability of possible policy termination.

The results that we have derived for different learning scenarios are given in relatively simple quantitative terms, mostly using counting of occurrence frequencies and elementary statistical measures. The relative simplicity of the results suggests that these can be directly and usefully applied to effective organizational policy evaluation and review for many situations.

APPENDIX A

The following provides the justifications of the results of Section III.

Let the random variable T be the number of observations preceding the first positive reward; i.e. T may be regarded as the waiting time to the first positive reward, measured in number of observations, then

$$\Pr[T = k] = pq^k, k = 0, 1, 2, 3, \dots \quad (1)$$

The probability generating function $G(z)$ of T is given by

$$G(z) = \sum_{k=0}^{\infty} \Pr[T = k] z^k = p \sum_{k=0}^{\infty} q^k z^k = \frac{p}{(1 - qz)}. \quad (2)$$

Note that after the occurrence of the first reward, the process probabilistically repeats itself again, so that we have for the waiting time W_r of the r th positive reward

$$W_r = \sum_{k=1}^r T_k, \quad (3)$$

where each T_k has the same distributional characteristics as T . From (Feller, 2008), the probability generating function of $G_r(z)$ corresponding to W_r may be obtained

$$G_r(z) = G_1(z)^r = \left[\frac{p}{(1 - qz)} \right]^r. \quad (4)$$

To get a better understanding of behavior specified above, it is useful to obtain the average waiting time W_r and its variance when r positive rewards are observed. From (4), the mean and variance of W_r can be derived

$$E[W_r] = G'_r(1) = \frac{rq}{p}, \quad (5)$$

$$\text{Var}[W_r] = G''_r(1) + G'_r(1) - G'_r(1)^2 = \frac{rq}{p^2}.$$

Furthermore, the probabilities $\Pr[W_r = k]$ may be readily obtained from the expansion of (4),

$$\Pr[W_r = k] = \binom{-r}{k} p^r (-q)^k, k = 0, 1, 2, 3, \dots$$

APPENDIX B

The following provides the justifications of the results of Section IV.

In order to attain h for either agent, the number of observations Ω will fall within the range

$$2m + 1 \leq \Omega \leq 4m + 1.$$

If f_k represents the probability that A wins at observation number $4m+1-k$, which occurs if and only if A scored $2m$ successes in the first $4m-k$ observations, and subsequently score a final success, then f_k is given by

$$f_k = \binom{4m-k}{2m} p^{2m+1} q^{2m-k}.$$

The probability that A reaches the threshold first, irrespective of the observation number, is therefore given by

$$P_m = \sum_{k=0}^{2m} f_k = \sum_{k=0}^{2m} \binom{4m-k}{2m} p^{2m+1} q^{2m-k}.$$

That is, P_m gives the probability that the learning is successful (i.e. agent A wins) according to *Rule B*.

Understanding Organizational Development With a Continuum of Care Model

Kwong Yuen Liu

Yee Hong Centre for Geriatric Care, Canada

INTRODUCTION

Most non-profit organizations move through a life cycle of stages that are comparable to human development (Born, 2000). These stages define the change of organizational processes that contribute to the evolution of non-profit organizations. Although these stages are well defined in the literature, the manner in which a non-profit organization transitions between stages is driven by a myriad of factors, such as: leadership, governance, financial capacity, and staffing (Simon, 2012). These factors influence not only the development of non-profit organizations, but also their long-term sustainability.

In this article, a case study of the Yee Hong Centre for Geriatric Care will be presented to illustrate its development throughout the non-profit organizational life cycle. The Yee Hong Centre was specifically chosen as its adoption of a continuum of care model has become one of the primary drivers of the organization's development. However, as with other non-profit organizations, the Yee Hong Centre continues to face new challenges in maintaining its current level of success. This article will provide a conceptual understanding of how the continuum of care model can be applied to contribute to the organization's sustainability.

BACKGROUND

According to Lester, Parnell, and Carraher (2003), most non-profit organizations follow a five-stage life cycle consisting of: existence; survival; success; renewal; and decline. Although the cycle is presented in a seemingly linear fashion, not all non-profit organizations proceed through the five stages in such a manner. In fact, some organizations may regress to an earlier stage or skip to a later stage, while others may remain in one stage for an extended period of time. Still, some organizations, such as the Yee Hong Centre, may transition through multiple stages, but remain far from the final stage of decline (Lester, Parnell & Carraher, 2003).

What accounts for the variance in organizational development? Simon (2012) argues that there are seven distinct factors that influence the development of a non-profit organization. These factors include:

DOI: 10.4018/978-1-7998-3473-1.ch017

- Governance: the role of the board of directors in driving the long-term planning and development of the organization;
- Leadership: the role of senior executives in translating the organizational mission into reality;
- Financing: the organization's source of funding and fundraising to sustain its operation;
- Administrative systems: the establishment of formal systems, procedures, and policies within the organization;
- Products and services: the tangible or intangible benefits that customers gain from the use of the organization's products and services;
- Staffing: the human resources required to sustain the operation of the organization; and
- Marketing: the organization's promotional and outreach efforts (Simon, 2012; Varga Consulting, 2017).

The importance of each factor and the influence that it exerts on the organization depend largely on the stage of development that the organization is at (Simon, 2012). For example, in early stages where an organization is only beginning to form, leadership is considered to be more important than staffing, as the organization requires strong leaders with the capacity to gather resources and translate their vision into reality. Over time, however, staffing eventually becomes more important as the organization grows in stability and human resources become necessary to maintain daily operation (Simon, 2012).

Regardless of the developmental stage, most non-profit organizations, including the Yee Hong Centre, must consider the seven aforementioned factors in order to successfully plan for long-term sustainability (Simon, 2012). However, what sets the Yee Hong Centre apart from other non-profit organizations is its adoption of a continuum of care model that has provided guidance for the organization's planning and delivery of services (Gulliford, Naithani, & Morgan, 2006). Since its establishment in 1994, the Yee Hong Centre has dedicated itself to a mission of "enabling Chinese Canadian and other seniors to live their lives in the healthiest, most independent, and dignified way, through [a] continuum of excellent, culturally appropriate care" (Yee Hong Centre for Geriatric Care, 2017). This continuum of services assumes that:

- Aging is a dynamic process;
- Needs differ between individuals and change across the life course;
- Holistic health includes not only physical, but also emotional, psychological, social, and spiritual well-being; and
- A continuum of services is necessary in order to meet these changing needs and promote quality of life (Liu, Wong, Chu, & Leung, 2017; Gulliford, Naithani, & Morgan, 2006).

With these assumptions, the Yee Hong Centre developed a diverse range of core and support services that cater to the changing needs of seniors and their families from retirement to end of life (see Figure 1) (Liu et al., 2017).

Core services form the foundation of the continuum and include: an active senior program, congregate dining, an adult day program, home support services and assisted living, long-term care, and residential hospice. Needs may change and seniors may be required to transition into other services that better meet their needs, as such, support services have also been developed to complement core services. These support services include: caregiver support and education, client intervention and assistance, friendly visiting, medical services, programs and services development, transportation, and volunteer development. Each of these services work in tandem to provide a seamless continuum of care that can address

Figure 1. The Yee Hong Centre's continuum of services (Liu et al., 2017)

The Continuum of Services

- Play Intervention for Dementia (PID)

the needs of seniors and their families at different points in the life course, in turn promoting their health and quality of life (Liu et al., 2017). This article argues that this model of care, which now serves as the organizational mission, has significantly driven the organization's growth and development. In the following section, a closer examination of the Yee Hong Centre's transition through the non-profit organizational life cycle will demonstrate how the continuum of care model has played an important role as a primary driver of organizational development.

CASE STUDY: YEE HONG CENTRE FOR GERIATRIC CARE

Stage One: Existence

The first stage of the non-profit organizational life cycle is marked by the ability to gather sufficient monetary and in-kind resources to support a newly developing organization (Lester, Parnell, & Carraher, 2003; Pacific Continental Bank, 2011; Varga Consulting, 2017). In the 1980s, when Dr. Joseph Wong observed that many Chinese seniors living in mainstream long-term care homes had unmet needs, he gathered support from friends and volunteers to advocate for the development of a culturally appropriate long-term care home (Liu et al., 2017). Although Dr. Wong's proposal to build a long-term care home for Chinese seniors was initially met with many obstacles, the support that he gathered from the community helped him to overcome them. The subsequent completion of a needs study also provided support for

Dr. Wong's proposal and, more importantly, demonstrated that a long-term care home is not sufficient to meet such a diverse range of needs. As a result, the first Yee Hong Centre was built in 1994 with a basic continuum of services that included not only a long-term care home, but also a community centre, social housing complex, and medical centre (Liu et al., 2017). Despite the uncertainty of the organization's existence at the time, the dramatic growth in community support generated enough momentum that drove the Yee Hong Centre into the next stage of organizational development.

Stage Two: Survival

In the second stage of the non-profit organizational life cycle, organizations attempt to establish internal processes and structures as well as their competitive advantage to distinguish themselves from competitors. At this stage, organizations strive to generate enough revenue to sustain operation (Lester, Parnell, & Carraher, 2003; Varga Consulting, 2017). Following the establishment of the Yee Hong Centre, a board of directors that governed the organization was formed (Yee Hong CARE-Learning, 2016). At the same time, staff and volunteer recruitment proceeded at a rapid rate in order to establish the necessary structures to sustain the Yee Hong Centre's operation. Other than securing government funding, Dr. Wong also established the Yee Hong Community Wellness Foundation to support the organization's fundraising and public relations efforts. This ensured a healthy mix of financial resources to sustain the operation of the Yee Hong Centre (Yee Hong CARE-Learning, 2016).

While these internal structures were being formalized, the Yee Hong Centre's continuum of services quickly expanded. Dr. Wong's initial vision of building a culturally appropriate long-term care home became a spring board for the development of a continuum of services that grew to include community services such as an active senior program, an adult day program, home support services, and caregiver support and education. This rapid expansion of services not only garnered increasing support from the community, but also secured additional funding to help the Yee Hong Centre pass the survival stage (Yee Hong CARE-Learning, 2016; Lester, Parnell, & Carraher, 2003; Varga Consulting, 2017).

Stage Three: Success

The third stage of success is defined by formalized organizational structures and processes. By the time an organization has reached this stage, it has successfully transitioned from a period of uncertainty to stability (Lester, Parnell, & Carraher, 2003; Varga Consulting, 2017). Multiple levels of management have been established, allowing senior executives to focus on strategic planning while middle management oversees the organization's daily operation (Lester, Parnell, & Carraher, 2003). A strategic plan has also been established to guide the development of the organization and maintain sustainability (Pacific Continental Bank, 2011; Varga Consulting, 2017).

The dramatic growth of the Yee Hong Centre during the initial two stages has led to a rapid expansion of the organization's continuum of services. Dr. Wong's vision evolved into the establishment of four long-term care homes and a community and professional services division that serve approximately 20,000 seniors and their families across Toronto every year (Liu et al., 2017). At present, the Yee Hong Centre maintains its status at the success stage by continuously expanding and improving its continuum of services to meet the changing and growing needs of seniors and their families. In particular, the Yee Hong Centre regularly promotes client engagement through the use of client satisfaction surveys, quality improvement meetings, and ongoing dialogue with seniors and their families. This allows the organiza-

tion to continuously review its continuum of services and make improvements that address the needs of seniors and their families.

Stage Four: Renewal

The fourth stage of renewal is a period of rejuvenation, innovation, and creativity (Lester, Parnell, & Carraher, 2003; Varga Consulting, 2017). At this stage, non-profit organizations are looking for new ways to reposition themselves in the sector in order to prevent a decline in success and possible spiral into bankruptcy (Lester, Parnell, & Carraher, 2003). This can occur in the form of change in any of the seven aforementioned factors that influence non-profit organizational development (Simon, 2012). For instance, changes in governance and leadership could prevent a non-profit organization from further decline by realigning the organizational mission with community needs and inducing positive change within the organization (Simon, 2012; Varga Consulting, 2017).

Although the Yee Hong Centre has not yet reached the stage of renewal, it must continue to look beyond its current success and be proactive about implementing measures that prevent decline. For instance, the organization has undergone various leadership changes since its establishment and each new leadership team has brought with it a new wave of changes that propelled the Yee Hong Centre into greater success. More recently, the current leadership team has begun exploring social enterprise opportunities as a means of maintaining sustainability and creatively meeting the changing needs of seniors and their families. Examples include developing a line of incontinence products for seniors and incorporating technology such as virtual reality to engage younger generations of seniors. All of these initiatives were developed based on client needs and aim to further strengthen the current continuum of services. Nevertheless, more proactive approaches that benefit the organization in the long run need to be taken if the organization is to sustain itself in this changing economy (Lester, Parnell, & Carraher, 2003; Struthers, 2003). In the following section, maintaining non-profit organizational sustainability, specifically using the continuum of care model, will be discussed.

SOLUTIONS AND RECOMMENDATIONS

Given the success of the Yee Hong Centre, it is natural to assume that the organization will be able to sustain itself in the long run. However, “the key to long-term sustainability is knowing and understanding the stage an organization is in, and taking steps to be successful within each phase” (Pacific Continental Bank, 2011). Recognizing that the Yee Hong Centre is at the stage of success does not imply that efforts to prevent decline are unnecessary. Rather, in an environment where resourcing patterns for non-profit organizations are ever changing, more proactive approaches must be taken to ensure that the Yee Hong Centre continues to flourish (Struthers, 2003). Coblentz (2002) states that institutional, financial, and moral sustainability are of utmost importance in planning for the future of a non-profit organization. All aspects must be managed equally well in order to maintain sustainability.

Institutional Sustainability

At the heart of every non-profit organization is a mission, a story of how the organization came into existence and what it attempts to achieve to better its community (Coblentz, 2002). A sustainable organization will have developed both short- and long-term strategic plans that guide the organization’s

activities and define the needed resources to achieve its mission. However, even with solid strategic plans in place, non-profit organizations must maintain a certain level of flexibility as their environment constantly changes. As such, strategic plans can only act as a guide to help organizations use their resources as effectively as possible (Coblentz, 2002).

At its current stage of development, the Yee Hong Centre continues to maintain a strong focus of its mission. The organization reviews its strategic and annual operating plans on a regular basis to ensure they continue to be aligned with its mission. However, it is the continuum of care model that will help guide the organization's strategic planning in the long run. Specifically, the model's assumptions that aging is a process and that needs change over the life course can offer valuable insight into the types of services the organization should provide to meet client needs, as well as how to provide them in the most effective and efficient manner. Effective strategic planning, in turn, will help translate the model's assumptions into practice, thereby providing a direction for how to maintain institutional sustainability.

Financial Sustainability

According to Struthers (2003), some of the most successful non-profit organizations have implemented various resourcing practices, such as fundraising, core resourcing, event driven revenues, and partnership resourcing, to maintain financial sustainability. The Yee Hong Centre, in particular, has historically focused on core resourcing and fundraising as its primary sustainable measures. The organization heavily relies on government funding to support many of its community programs and long-term care, while its foundation regularly hosts fundraising events to generate sponsorships and donations. Nevertheless, an overreliance on any resourcing practice can prove detrimental if the resource is withdrawn or reduced (Struthers, 2003). In today's changing economy, it becomes paramount for non-profit organizations to diversify their resources to avoid any risk of bankruptcy or long-term deficit (Coblentz, 2002).

Despite a traditionally heavy reliance on core resourcing and fundraising, the continuum of care model can offer new directions for diversifying the resourcing practices of the Yee Hong Centre in order to maintain financial sustainability. Striving to provide a comprehensive and effective continuum of services requires a thorough understanding of the external environment and the needs of clients. This understanding can pinpoint the organization towards new areas of development that could create opportunities to either bring in additional resources or to improve the organization's financial management practices (Struthers, 2003; Coblentz, 2002). For instance, the organization has previously identified a duplication of services within the community (i.e., providing the same service to the same group of clients within the same geographic area). Rather than continuing to pursue this path of service duplication, the organization instead diversified its resourcing practices by increasing its partnerships with local communities and educational institutions to enhance the efficiency and accessibility of services. This not only provided an additional resource for the organization, but also improved the quality of services. In the long run, the Yee Hong Centre will need to continue to improve its financial management practices to maximize revenue while generating additional sources of funding, such as grants, user fees, and social enterprise initiatives, to support financial sustainability (Coblentz, 2002).

Moral Sustainability

Institutional and financial sustainability must be coupled with strong human resources if a non-profit organization is to achieve long-term sustainability (Coblentz, 2002). It is the staff and volunteers that help non-profit organizations to realize their mission and achieve financial stability. Moral sustainability

is about managing staff morale and requires strong leadership, effective and transparent communication at all levels of the organization, as well as clear expectations, policies, and procedures for staff to perform competently (Coblentz, 2002).

The Yee Hong Centre has always prided itself in a strong team of staff and leaders who are highly committed to the organizational mission. To date, it has grown into a multi-site organization that serves approximately 20,000 seniors and their families across Toronto every year (Liu et al., 2017). One of the main drivers of this growth of human resources is the continuum of care model. Although establishing continuity of care continues to be a challenge (Bergman et al., 1997), the Yee Hong Centre's persistence in developing a comprehensive continuum of services has attracted many likeminded staff with the same passion and dedication to the organizational mission. To continue to strengthen moral sustainability, the Yee Hong Centre can apply the same principles behind the continuum of care model to staff management. By enhancing the organization's understanding of staff needs and goals, it can implement appropriate practices to improve staff support and development. Ultimately, this can enhance overall staff morale and contribute to long-term moral sustainability (Coblentz, 2002).

FUTURE RESEARCH DIRECTIONS

Continuity of care is becoming increasingly prevalent in the senior service sector (Bergman et al., 1997; Leatt, Pink, & Guerriere, 2000). Research has demonstrated a growing need for a better coordination of services to improve the effectiveness and efficiency of care (Leatt, Pink, & Guerriere, 2000; Veras et al., 2014). Although the community at large has yet to implement a well-coordinated system of service delivery, the Yee Hong Centre has taken the first step by translating the continuum of care model into practice (Leatt, Pink, & Guerriere, 2000). Over time, the model has become an integral foundation that continues to guide the organization's planning and delivery of services.

As the senior population continues to grow and change, the Yee Hong Centre will, however, need to place a heavier focus on sustainable practices to maintain its success. The organization will be required to engage in long-term strategic planning, taking into consideration the current funding landscape and how to best make use of resources to meet the needs of a growing senior population (Struthers, 2003). Transition planning may also become another point of focus as seniors live longer and healthier lives. This may suggest a change in the focus of services offered as well as in how to support seniors as they transition through their life course (Veras et al., 2014). Other than staying current with the changing demographics of clients, the Yee Hong Centre may find it helpful to review internal processes to promote employee health and wellness (Coblentz, 2002). In addition to taking proactive measures to address the external environment, the organization must plan ahead in order to prepare for employees who are considering retirement in the near future as well as younger employees who may wish to continue to further their career within the organization.

Although this article focused upon one particular non-profit organization, it would be of value to study the development of other organizations and how they have coped with various challenges over the course of their development. Of particular interest is the implementation of the continuum of care model at different levels of systems and how it may benefit other non-profit organizations in their development. Future research on the effectiveness of the continuum of care model could bring valuable knowledge to leaders in the non-profit sector.

CONCLUSION

The Yee Hong Centre has embarked on a journey of growth and development. Despite the obstacles that Dr. Wong and his supporters faced along the way, they marched forward with their dream of providing culturally appropriate care for Chinese seniors. Over the course of the Yee Hong Centre's development, the continuum of care model proved to be an important contributor in propelling the organization forward. More importantly, the model also contributed to the development of sustainable measures for the organization. Specifically, this article examined the Yee Hong Centre's institutional, financial, and moral sustainability and how they can be effectively managed using the continuum of care model as a blueprint. With an ever changing funding landscape and community needs, sustainable non-profit organizations will need to stay ahead by understanding their organization within the life cycle as well as establishing long-term strategic plans that efficiently and effectively make use of resources to achieve the organizational mission. In the future, it would be valuable to examine and compare the development of other non-profit organizations and the application of the continuum of care model at different levels of systems.

KEY TERMS AND DEFINITIONS

Continuum of Care: A model of care that provides a seamless transition of health and social services for clients.

Core Resourcing: A type of resourcing practice that funds the primary operations of an organization.

Non-Profit Organizational Life Cycle: A developmental cycle for non-profit organizations that defines distinct stages and their associated activities and processes.

Resourcing Practice: A practice to gather resources that provide support to organizational activities.

Social Enterprise: A type of organization that uses commercial methods to maximize social impact.

Strategic Plan: A plan that defines an organization's direction and how it will be translated into practice.

Sustainability: The ability of an organization to maintain or enhance current operations towards the pursuit of its mission.

Does the Organizational Change Induced by the Pre-Implementation of an IS Proceed as a Planned Process?

INTRODUCTION

The pre-implementation process of an IS is characterized by procedures of selection and evaluation, which is rather in a pattern of change in a planned process. However, the research on organizational change gave rise to several approaches according to which, the change can be explained by other processes (political, interpretative, incremental and complex).

By this research, the authors seek to answer the question: Does the induced change in the context of the GBS pre-implementation process refer to a planned process or may the observed change have other characteristics relating to other explanatory processes of change?

The purpose of this research is to explain the progression of change during the pre-implementation phase of a GBS that is envisaged as a planned process in the literature. Better empirically describing this process allows managers to better target change support actions during this phase. In order to achieve the objective of the research, a qualitative study by case study is conducted in Basic Bank, one of the leading bank establishments in the Tunisian market as part of its project of implementation of a GBS especially during the process of its pre-implementation.

Based on this result, it is recommended to practitioners who wish to lead a change within their organizations to envisage the managerial actions from the outset of the project in order to reduce the potential conflicts of interest between actors.

BACKGROUND

The pre-implementation evaluation of an Information System (IS) is of major importance (Mussi et al. 2018). Indeed, during this phase, it is possible to identify issues which were likely to affect implementation and use of the new system (Mussi et al. 2018). The pre-implementation process, as part of a project to implement integration solutions IS such as Global Banking System (GBS), consists in a study leading to the selection of an ERP software, software developer, and consultant (Hustad and Dag Hakon, 2011; Mourrain and Deltour, 2016). This process is characterized by the specifications preparation, the target and the functional coverage definition, the software developer choice, etc. (Al Mashariand and

DOI: 10.4018/978-1-7998-3473-1.ch018

Al- Mudimigh, 2003). Markus and Tanis (2000) claim that failures in the pre-implementation process may escalate the rest of the project. According to Velcu (2010), the failures in this process could lead to an overall unsuccessful implementation. The ERP pre-implementation process has proved to be a particularly critical stage (Markus and Tanis, 2000; Verville et al., 2007; Razmi and Sangari; 2013; Mourrain and Deltour, 2016; Mdimba et al., 2017). Indeed, it's a demanding *"process which required a high level of knowledge and competencies about the system, and tough negotiation processes between project leader, vendor, resellers and consultants"* (Hustad and Dag Hakon, 2011, p.1). This can generate a change in the organization.

This change is characterized by the tracking methods and selection procedures and evaluation of the software package (Kaur and Mahanti, 2008, Kutlu and Akpinar, 2009), which is rather in a pattern of change in a planned process (Kotter, 1995; Soeini and Miri, 2011; Pichault, 2013). However, the research on organizational change gave rise to several approaches sometimes paradoxical. According to these approaches, organizational change can be explained by other processes such as the political process, the interpretive process, the incremental process and the complex process (Vas and Ingham, 2002; Vas and Jaspart, 2010; Pichault, 2013). Organizational change during the pre-implementation process of the ERP is little studied in the literature. According to Hustad and Dag Hakon (2011), the pre-implementation process of the ERP projects need for more empirical studies.

PRE-IMPLEMENTATION PROCESS OF AN INTEGRATED SYSTEM AND EXPLANATORY PROCESS OF CHANGE

In this section, the authors present the theoretical framework, describe the research methodology and explain the results and their discussion.

Theoretical Framework

The theoretical framework of this research has been organized into two subsections. In the first, the authors describe the main characteristics of the pre-implementation process of an integrated system. The second is devoted to the presentation of the different explanatory processes of change.

Description of the Pre-implementation Process of an Integrated System

The implementation of integrated systems such as ERP had induced organizational change since the selection of the software until its effective use. During the pre-implementation process, evaluation and selection of the software are an essential element of ERP projects. According to Wei et al. (2005, p.47), *"companies must choose a flexible ERP system and a co-operative vendor that is responsive to customer needs"*. The system selection should be made in alignment with the competitive strategies and goals of the enterprise (Wei et al., 2005). These authors apply the Analytic Hierarchy Process (AHP) method of Saaty (1980) for dealing with the ambiguities involved in the assessment of ERP. This method *"synthesize decision makers' tangible and intangible measures with respect to numerous competing objectives inherent in ERP system selection and facilitates the group decision-making process"* (Wei et al., 2005, p.49).

Several authors characterize this process by tracking method and selection and evaluation procedures (Kaur and Mahanti, 2008, Kutlu and Akpinar, 2009), which is rather in a pattern of change in a planned

process. However, the literature on organizational change shows the existence of several explanatory processes of change.

The Explanatory Process of Change

The works on the change can be divided into two perspectives: the works on the study of the contents of change and others dealing with its process. Studies forming part of the first perspective neglect the temporal dynamics on the progression of change that is considered by the works on the process of change. These studies consider the change as the passage of a state 1 to a state 2 (Thiéart, 1980). This passage records an empirical observation of a difference in form, quality or state of an entity (individual work, group work, the strategy of an organization, program, product, or an entire organization) in the time (Van de Ven and Poole, 1995). In order to operationalize this empirical observation concerning the progress of change in time, several authors (Lewin, 1947; Weick, 1969) recommend recourse to the cutting process in different phases.

This research is a continuity of studies dealing with change as a process. A summary of studies on this perspective sets the process of change as a planned response to environmental pressures and to the forces on the inside of the organization (Alas, 2008) thus reflecting the way to go between a departure state and arrival state (Thiéart, 1980).

Van de Ven and Poole (1995) found the existence of a theoretical pluralism to explain the progress of change. They identified four theories that may serve as building blocks for explaining processes of change in organizations: life cycle, teleology, dialectics, and evolution. This theoretical pluralism could lead to a partitioning of perspectives leading to isolated research lines.

To understand the progression of change, Van de Ven and Poole (1995) argue in favor of the mobilization of these different theories. These theories allow explaining and illuminating the theoretical underpinning of “the evolution of organizational change”. Based on these approaches as well as on the literature on organizational change, several authors have proposed the explanatory process of the of change progression (Vas and Jaspert, 2010; Pichault, 2013). The explanatory process of change may thus be defined as a modeling of the change progression.

Five explanatory processes of change are identified from the literature review: the planned process, the political process, the interpretive process, the incremental process, and the complex process.

- According to the planned process, the progression of change is marked by a succession of phases, monitoring of procedures, setting of objectives, participation stakeholder and the possibility of amending and adapting along the way.
- According to the political process, the change progression is marked by power struggles, continuing negotiations between the interests of different stakeholders within the organization and a regular mobilization of the project steering instances.
- According to the interpretative process, the progression of change is marked by a consideration of the actors’ perceptions, their actions and reactions, information on the different possibilities objectives achievement and justification of the choices made.
- According to the incremental process, the progression of change is marked by building on previously developed choice and the impact of other projects carried out in parallel within the organization (sharing of resources).
- According to the complex process, the progression of change is marked by unexpected phenomena, stops and blocking.

For this research, the authors seek to study the induced change in the context of a pre-implementation process of the GBS to verify whether it pursues a planned process or the observed change may have other characteristics that fall within other explanatory processes of change (political process, interpretative process, incremental process, and complex process).

Research Methodology

In this section, the research methodology, data collection methods, the coding device, the research context in Basic Bank and the project of implementation of the GBS that the authors followed during its pre-implementation process are presented.

Search Method with a Single Case Study

Yin (2003) advocates the single case method if the study focuses on understanding a process in its real context and for which the boundaries between the studied phenomenon and its context are not obvious. The selection of case is dictated by the research question that recommends that preferably the company is currently conducting a change project. Basic Bank, which the authors integrated while working on the project of implementation of GBS, meets this criterion.

Data Collection

Data collection is performed by retrospective semi-structured interviews conducted with 17 members of the project team, a non-participating observation and document analysis.

The authors seek to understand the organizational change by mobilizing the explanatory process of change as part of GBS implementation project during its pre-implementation process. Thus, the authors choose to interview project team members since they are better informed. This team is composed of a business pillar and a technical pillar. The business coordinator and technical coordinator ensure project management. It is organized into 21 functional domains (technical and business) with 2 transverse domains (change management and target organization). Each functional domain is formed of one or two leader(s) and contributors. Interviews are conducted with the senior management (Project Owner), project management (business coordinator and technical coordinator), and 14 domain leaders. Each interview lasted from one to two hours and were all recorded and immediately transcribed.

The observed facts, remarks, comments and interpretations resulting from the interaction with the staff as well as informal discussions are systematically recorded in a research paper. The collected data were subjected to content analysis (Bardin, 1993).

Data Coding

As advocated by Miles et al. (2013), the condensation of data was carried out by thematic coding. Prior to empirical data collection, a code starting list was established based on a review of the salient literature. The chosen unit of analysis is a sentence extract or even a paragraph of the transcript.

The authors have chosen more inferential coding in order to identify trends (patterns) that can be accredited to any proposed theoretical processes (Vas and Ingham, 2002). The descriptive inference, a methodological approach inspired both from grounded theory (Glaser and Strauss, 1967) and techniques for analyzing qualitative data (Miles et al., 2013) assumes an interactive relationship between descrip-

tion and explanation (Vas and Ingham, 2002). The authors add that descriptive inference also highlights the important role of interpretation that allows a better understanding of the studied phenomenon. The authors have mobilized the indicators proposed by Pichault (2013) that allowed classifying interview extracts according to the five explanatory processes of change derived from the literature. The authors have also opted for multiple coding when a text segment seemed to simultaneously represent several categories to avoid “forcing” the data to a particular category (Vas and Ingham, 2002).

Two types of coding were performed (Miles et al., 2013):

- A multiple coding was performed by the authors to ensure the internal consistency of the coding. A month later, all the interviews were subject to a second coding. The confrontation between the first coding and the second one has defined a reliability coefficient of 90 percent.
- A multi coding was independently performed by a second management science researcher so as to ensure the coding reliability: extracts randomly taken from interviews are coded by a second researcher in management science. The reliability coefficient calculated between encoders is 82 percent.

The calculated reliability coefficient by both coding types was superior to 82%; this would justify the reliability of the results (Miles et al., 2013).

Case Overview Basic Bank and Project of Implementation of GBS

Founded in 1976, Basic Bank is one of the leading bank establishments in the Tunisian market and one of the largest financial institutions in North Africa. It offers its customers (individuals, SMEs, and big companies) a comprehensive and innovative range of products for its activities in Tunisia and abroad. It often acts as a pioneer in the introduction of new banking goods and services in the Tunisian market (e.g. credit cards, remote banking products, and bank assurance products). Basic Bank employs 2,454 persons and is based among other things on a network of more than 1,000 correspondents worldwide. It has owned since numerous years, one of the first information systems that have been customly designed to meet the customs' needs and specificities by its teams. Today, this system no more allows the bank to grow serenely and with greater efficiency. To support its growth and development, Basic Bank chooses to implement an integrated solution. The product that will be set up is Global Banking System (GBS), that is to say, an integrated information system specifically adapted to banking and covering most requested features (customer and accounts management, agency operations, ...) as well as regulatory aspects (accounting). The solution that Basic Bank has chosen at the end of a selection process is the “P24¹” software of developer “Package²”. P24 is open and integrated software that offers a wide and rich functional coverage. It is implemented in more than 600 banks in the world.

Search Results

This section is devoted to explaining the observed change during the process of pre-implementation GBS.

Planned Process

Basic Bank has appointed a Deputy Managing Director (DMD) to oversee the project and define the decision-making bodies. The DMD has appointed, in turn, a business coordinator and a technical coordinator to carry out this project.

During this process of pre-implementation, the people involved have developed tender specifications that were sent to the software developer. These tender specifications provide a description of the existing IS, organization and project planning. They also set the framework of the provision, the characteristics of the project and the conditions for its success.

Data show that this process corresponds to a cut process, well-studied way, in several stages. Through the collected data, the authors reconstructed this process which lasted 7 months (Figure 1).

Figure 1. Pre-implementation Process of Global Banking System

The framing strategic orientations are the first stage of the pre-implementation process of GBS. In this stage, it was a question to deepen and clarify the strategic objectives defined for the bank, finalizing the project scope and identifying the highlights of the scenario construction. This stage culminated in the declination of the strategic challenges into operational objectives and identification of IS impacts. Members of the project team, with the assistance of external consultants, defined **the project driving modalities**. In this second stage, they have structured the project in functional areas, organized project governance, designated participating resources to the project (business and IS) and planned the meetings by functional areas.

Members of the project team have developed a list of workshops to perform, workshop participants and deadlines. The third stage corresponds to the **definition of the target and scenarios construction**. This is to determine the functional target by functional area and the major challenges by business. This stage culminated in the finalization of the overall target and scenarios construction of each functional area.

The fourth stage is the **software developer's pick**. In the preparatory work for this stage, it was a question to validate and/or complete the list of targeted software developers, adapt the content and modalities of the consultation, update and complement the existing consultation file for sending to software developers and prepare workshops examination of tenders. Then the members of the project team began the deepening works. This was to follow up requests for information, strip the offers using the test set out in the fourth stage to select the best performing software developers, identify the key questions addressed to the software developers as well as additional information, organize the deepening workshops and prepare a folder of choice for the senior management. Finally, the last stage corresponds to the **preparation of the implementation**. It is devoted to the definition of the optimal trajectory to reach

the target, structuring of the building site in operational projects (objectives, scope, priorities, project actors, ...), prioritization of all functional and technological projects and the first estimate of the teams to be formed. In parallel to all of this work, there are two transverse stages namely the **steering project** stage and the **change management** stage. The design of steering tools, team leadership and monitoring the overall consistency of deliverables represent the preoccupations of the **project steering** stage.

In the stage of **change management**, it was a question to design and implement the communication on the project. At the end of this pre-implementation process, Basic Bank selected the P 24 system, and signed the contract with its software developer “Package”. The agency area leader said: “This decision was made in the announced times”.

This period is characterized by:

- A cutting multi stage;
- A formal identification of a structure dedicated to the project direction directly attached in the senior management;
- A clear definition of the role of project director;
- A specification of a tender specification;
- And a definition of a precise timetable.

Thus, the planned process explains the change progression during the process of pre-implementation of the GBS. However, the change during this process is also characterized by continuous negotiation between the different actors involved. This aspect is a feature of the political process.

Political Process

During the pre-implementation process of the GBS, there has been a great mobilization of various actors of the bank representatives a variety of interests. This mobilization of people appears in the formation of a project team, the temporary participation of several individuals from different bank structures and the specification of the decision making bodies of the project. The operation mode of these participants is based essentially on organizing meetings as part of various committees in order to follow project progress, validating and exchanging the Broad Guidelines and taking major decisions related to the project. 11 interviewees specify that, as part of the first meetings concerning the strategic study of the redesign project of Information System (IS), the makers of Basic Bank (strategic owner, senior management and direction of an information system) were faced with three possible scenarios:

- an iso-functional migration of the current system: improvements to the current operating system;
- “*The best of breed*”: choose the base that will adopt the bank’s referential and around which the most appropriate applications on the market for Basic Bank (Credit, market, guarantee, ...) will be integrated;
- Acquire a *Global Banking System (GBS)*.

The existence of these three alternatives creates coalitions each of which defends a particular choice, as shown in the following interview excerpt conducted with the strategic owner: “*I was among the people who fiercely defended a development in-house. I pushed towards the alternative to rewriting our programs by our teams for not being at the mercy of the people from outside [...] The new director of the information system did not accept. He showed much concern about the alternative of internal*

development. He oriented the decision to purchase a Global Banking System". Once the final decision is made in favor of the acquisition of GBS, the project works is organized around 12 functional areas, a transverse area and a technical area in order to choose the best system for Basic Bank. The leader 2 of area tests Coordination says: *"around 90 people, the best employees of the bank (business and technical) have been the drivers of the choice of our new system"*.

The examination of tenders was effected by carrying several meetings. Each of them lasted a half day per domain. 14 meetings were conducted: 12 meetings were dedicated to functional areas, a meeting to discuss cross cutting themes and a meeting to discuss the technical aspects (internal document). This stage, characterized by several discussions and negotiations, culminated in the pre-selection of the two best offers namely: SAMW³ and P24. On the deepening stage, the project team asked the pre-selected software developers for demonstrations and case studies to better understand the functionalities of the different systems. These demonstrations and case studies are conducted in the premises of Basic Bank. The leader of the area Controls, Security and Habilitations specifies: *"there have been meetings with suppliers to present their products. Each gave four presentations"*. Visits, at other banks in Tunisia and abroad of similar size to Basic Bank, already using the system are performed. These visits were an opportunity to see work in real exploitation, the two pre-selected systems and that for the entire perimeter to cover. This stage is characterized by the emergence of several negotiations between actors. Indeed, all the interviewees emphasize the specificity of the Tunisian context regulatory, as described by the leader of the area Means of payment: *"The currency regulation (check, teleclearing) does not exist abroad"*. This specificity leaves emerge the formation of two major interest groups:

- A set of actors want to acquire the SAMW system because P24 does not exist in the Tunisian market. In fact, the "Package" software developer does not know the specificities of the Tunisian regulations. So some people have shown some concern for such a choice. The strategic owner says: *"computer scientists and people of administration preferred SAMW because there are Tunisian banks that use this system"*.
- Businesses are for the purchase of P24, as expressed in the strategic owner: *"I have fought for P24 because I liked it in the "area international". On this area, he was the best compared to other"*.

The final choice made by the senior management was in favor of the P24 system of the software developer "Package".

The pre-implementation process of the GBS is characterized by arbitration and negotiations between the actors involved. Thus, the political process explains the progression of change during this process. For a complete understanding of the progression of change that characterizes this pre-implementation process of the GBS, the data show the importance of the mobilization of the interpretive process.

Interpretative Process

The pre-implementation process of the GBS is sustained by a collective representation of the environmental threat. This collective representation is attributable to the emergence of the Basel II norms. These norms impose on banks the calculation of new ratios, which necessitates the use of updated information and particular modes of calculation that escape the current, IS of Basic Bank. The collective representation of the environmental threat is also driven by Tunisian regulations.

Indeed, the banking sector knew the emergence of the law ascribing the approval in favor of universal banking. This law favored the establishment of a more liberal environment for the execution of banking

activities by suppressing the legal separation among the “development banks” and “commercial banks”. From now on, each establishment is accredited as a “universal bank” that can specialize according to its strategic choices. This approval as universal banks increases the competition.

This competition is found more severe because of the privatization process of the banking sector that is accelerating by opening itself to foreign partnerships. As part of this bank privatization movement in recent years, the Tunisian State has undertaken the cession of important parts of the capital of some banks in favor of foreign banks (Central Bank of Tunisia, 2015).

Bank staff recognizes the urgency of recasting their IS. All interviewees say that the current IS showed off its operational limits and has become deadpan. It represents a heavy weight ahead of the development of the profession. Thus, the current IS of Basic Bank is a major obstacle to the development of its various activities. This has favored the emergence of a collective need in Basic Bank of the necessity of change. This collective representation of the need to implement a GBS to face competition facilitates the achievement of a consensus. Indeed, despite the negotiations in the process of system selection, the final decision of the acquisition of P24 was taken in the announced deadlines. 15 interviewees point out that the selection system is based on a folder of objective choice. The people involved in this process analyzed the responses of the software developers on the basis of five criteria:

- functional coverage of the system;
- its technical characteristics;
- the project approach for its implementation;
- the soundness of the software developer and;
- the financial offer.

The justifications for the choice to carry out has required analysis and convincing approach, as expressed by the leader of area Agency: *“a comparison between the two solutions in connection with the bank’s needs was made in depth”*. The different areas have classified software developers according to a fixed rating scale.

The teams that worked on the pre-selection of the system proposed recommendations to the senior management who chose P24 by publishing the reasons for that choice in a circular note to all staff of Basic Bank: *“thanks to the continuous mobilization of Basic Bank teams and on the basis of a folder duly educated and objectified that we were able to take our decision. The package offers a wide and rich functional coverage, a coherent project approach and a competitive financial offer. P24 is also an open and highly integrated information system”* (Senior management). The justifications put forward in the different choices made by the bank show that change is characterized by the generation of a shared vision about the project among stakeholders, as expressed by the leader of area Agency by giving its opinion on the choice of P24: *“I am convinced that the Bank has made the best choice by opting, as part of the overhaul of its information system for the implementation of GBS P24 which has the advantage of being an integrated system, open and scalable,...”*.

The change during the pre-implementation process of GBS is characterized by:

- The propagation of a collective representation as to the need of the overhaul of IS of the bank ;
- The justification of the different choices made as part of the selection of the new system.

The planned process, political process, and interpretative process explain the change during the pre-implementation process of the GBS.

Discussion of Results

The planned process explains the change during the pre-implementation process of the GBS. This is explained by the importance of planning in change projects (Vas and Ingham, 2002; Andreeva, 2008; Vas and Jaspert, 2010; Pichault, 2013). The planning effort is first manifested by the appointment of a project manager and construction of a project team to ensure the change implementation (Pichault, 2013). Then the planned change is characterized by the development of tender specifications, the setting of a budget envelope and the defining a precise timetable (Pichault, 2013). Finally, the planned approach is an approach characterized by a cutting phase (Vas and Ingham, 2002; Pichault, 2013). For each, the direction sets interim targets (Vas and Ingham, 2002; Pichault, 2013).

The political process also explains the change during the pre-implementation process of the GBS. The result is explained by the existence of a diversity of actors involved (senior management, business, IT experts, consultants, etc.) in conducting the project (Pichault, 2013). It is also explained by the emergence of coalitions and conflicts of interest in the conduct of change (Vas and Ingham, 2002).

The change during the pre-implementation process of the GBS is also explained by the interpretative process. Indeed, the change is characterized by the appearance of a climate marked by a collective interpretation of the urgency of change. The shared collective representation is provided by mobilizing the changes that have characterized the banking sector (increased competition, the Basel II norms).

This result confirms the statement of Pichault (2013) which found that the emergence of the interpretive process in the change experienced by COM 2010 is explained by a collective representation of environmental threats (competition, deregulation, etc.)

FUTURE RESEARCH DIRECTIONS

Based on this result, it is recommended in future research to follow the evolution of change throughout the process: from pre-implementation of change to its consolidation. This will provide a dynamic model showing the evolution of change throughout the process of implementing a new IS. Such a research can serve as a basis to other future researches dealing with change management with the aim of defining managerial actions adapted to the evolution of change so as to succeed it.

It is also recommended to practitioners who wish to lead a change within their organizations to envisage from the outset of the project the actions of the change management for reducing the conflict of interest and manage conflicts between actors. It is also recommended to the members of the project team and the senior management to explain and justify the choices and make collective decisions to ensure a shared collective representation. This allows adhering all the actors to change and accordingly minimize resistance to change.

CONCLUSION

This research focuses on explaining the progression of the change induced in as part of a pre-implementation process of a GBS. Particularly, it is to check whether the observed change pursues a planned process or it may have other characteristics which fall within other explanatory processes of change (political process, interpretative process, incremental process, and complex process).

Table 1. Chronological matrix of pre-implementation process of the GBS

		Structuring of the project		Choice of a software solution			Preparation for implementation
		Framing strategic orientations	Defining project driving modalities	Definition of the target and scenarios construction	Software developer's Pick/ Preparation phase	Software developer's Pick/ Deepening phase	
Explanatory process of change	Planned process	- Decline of the strategic challenges into operational objectives and identification of impacts IS ; - Finalization of the project scope.	- Organize the project in functional areas; - Designate the participating resources (businesses and IS) ; - Elaboration of the list of workshops, participants and planning.	Preparation of a construction scenario			Macro implementation plan.
	Political process			- Conducting functional workshops for the determination of functional target by functional area and the major challenges by business. - conduct technical workshops.		Launch of negotiations for the selection of the software developer.	
	Interpretative process				- Update the consultation file. - Elaboration of grids and conditions for counting. - Pre-selection and preparation of deepening workshops software developers / operational	- Discussions on the scenarios: insurance of a shared collective vision. - Justification of proposed choice: folder of choice objectified.	

To this end, the authors have integrated a Basic Bank, the leader of the Tunisian market bank as part of its project of implementation of a GBS especially during the process of its pre-implementation. The results showed that during this period the change is explained by the planned process, political process and interpretative process (Table 1).

According to Table 1, besides the prepared planning (goals to be achieved, deadlines to be met), the change was characterized by the appearance of conflicts of interest and negotiations to select a software

developer. The change was also characterized by the intervention of the senior management to justify the choices made. This has let emerge a collective change representation by the actors. The change in the pre-implementation process of the GBS is thus explained by the planned process, political process and interpretive process.

The results of this research enrich the previous work on the study of change during its launch phase which envisages it very often as a planned process.

KEY TERMS AND DEFINITIONS

Change Process: Planned response to environmental pressures and forces within the organization (Alas, 2008), translating the path from departure to arrival.

Complex Process of Change: Change is marked by unexpected phenomena, stops and blocking.

ERP: Set of application software modules with an integrated architecture used by an organisation as their primary engine for integrating data, business processes and information systems across its business value chains in real time (Ngai et al., 2008).

Explanatory Process of Change: The modeling the progression of change.

Global Banking System: Enterprise Resource Planning (ERP) Systems in Banking sector.

Incremental Process of Change: Change is marked by building on previously developed choice.

Interpretative Process of Change: Change is marked by a consideration of the actors' perceptions.

Planned Process of Change: Change is marked by a succession of phases, monitoring of procedures and setting of objectives.

Political Process of Change: Change is marked by power struggles and continuing negotiations between the interests of different stakeholders within the organization.

Automating the Generation of Test Items

2

Hollis Lai

University of Alberta, Canada

Mark Gierl

University of Alberta, Canada

INTRODUCTION

With an ever increasing demand for more knowledge in our economy, organizations require methods of assessment to evaluate the skillset of their workers to produce new ideas, make new products, and provide new services. The ability to create these ideas, products, and services will be determined by the effectiveness of our educational programs. Education provide students with the knowledge and skills required to think, reason, communicate, and collaborate in a world that is shaped by knowledge services, information, and communication technologies (e.g., Binkley, Erstad, Herman, Raizen, Ripley, Miller-Ricci, & Rumble, 2012; Darling-Hammond, 2014). Educational testing has an important role to play in helping students acquire these foundational skills. Educational tests, once developed almost exclusively as a right-of-passage to satisfy demands for accountability and outcomes-based summative testing, are now expected to provide teachers and students with timely, detailed, formative feedback to directly support teaching and learning. With an increasing focus on formative learning principles being adopted to guide our educational testing practices, where assessment-related activities provide constant and specific feedback to modify and improve learning, assessments are being administered more frequently (Black & Wiliam, 1998, 2010). But when testing occurs more frequently, more test items are required. These additional test items must be created efficiently and economically while maintaining a high standard of quality. Fortunately, this requirement for frequent and timely educational testing coincides with the dramatic changes occurring in educational technology. Developers of local, national, and international educational tests are now implementing computerized tests at an extraordinary rate (Beller, 2013). Computerized testing offers many important benefits to support and promote key principles in formative assessment. Computers permit testing on-demand thereby allowing students to take the test at any time during instruction; items on computerized tests are scored immediately thereby providing students with instant feedback; computerized tests permit continuous administration thereby allowing students to have more choices about when they write their exams. In short, developments in computing technology enables the infusion of formative principles into our testing practices that would not have been previously possible.

Despite these important benefits, the advent of computerized testing has also raised formidable challenges, particularly in the area of test item development. Tests now require access to large numbers of diverse, high-quality test items to implement computerized testing as items are continuously administered to students. Hundreds of items are needed to develop the test item banks necessary for computerized testing. Unfortunately, creating test items is a time consuming and expensive process. Each individual item is written, initially, by a content specialist and, then, reviewed, edited, and revised by groups of content specialists (Gierl & Lai, 2016; Rudner, 2010). Hence, item development has been identified as one of the most important problems that must be solved before we can fully migrate to computerized

DOI: 10.4018/978-1-7998-3473-1.ch019

testing because large numbers of high-quality, content-specific, test items are required (Haladyna & Rodriguez, 2013; Webb, Gibson, & Forkosh-Baruch, 2013).

One emerging test item development method used to address this challenge is *automatic item generation* (AIG) (Gierl & Haladyna, 2013; Irvine & Kyllonen, 2002). AIG is a relatively new but rapidly evolving research area where cognitive and psychometric modeling practices guide the production of tests that include items generated with the aid of computer technology. Research on AIG has adopted different perspectives, including the use of natural language processing and artificial intelligence (e.g., Gütl, Lankmayr, Weinhofer, & Höfler, 2011; Moser, Gütl, & Lui, 2012; von Davier, 2018), frame-semantic representations (e.g., Cubric & Toasic, 2010; Higgins, Futagi, & Deane, 2005), schema theory (e.g., Singley & Bennett, 2002), and semantic web-rule language (Zoumpatianos, Papasalouros, & Kotis, 2011; Leo et al., 2019). The purpose of this chapter is to describe and illustrate the most practical method for generating test items, which is template based. By template-based AIG, we mean methods that draw on *item models* to guide the generative process. Gierl and Lai (2013, 2016, 2018) developed a three-step process for template-based AIG. In step 1, content specialists create a cognitive model for AIG. A cognitive model is a representation that highlights the knowledge, skills, and content required to generate new test items. In step 2, an item model is developed to specify where the cognitive model content is placed in each generated item. An item model is a template that highlights the variables in a test item that can be manipulated to produce new items. In step 3, computer algorithms place the cognitive content into the item model. With this process, hundreds of items can be created from a single item model. The purpose of this chapter is to describe how AIG can be used to generate test items using the selected-response (i.e., multiple-choice) format. To ensure our description is both concrete and practical, we illustrate template-based item generation using an example from the complex problem-solving domain of the medical health sciences. The chapter is concluded by describing two directions for future research.

BACKGROUND

Gierl and Lai (2013, 2016, 2018) described a three-step approach for template-based AIG. In step 1, a content specialist creates a cognitive model for AIG. In step 2, an item model is developed to specify where the cognitive model content is placed in each generated item. In step 3, algorithms place the cognitive content into the item model.

Step 1: Identify Content For Item Generation

To begin, the content for item generation is identified by the content specialists. This content is identified using design principles and guidelines that highlight the knowledge, skills, and abilities required to solve problems and perform tasks in a specific domain. A cognitive model for AIG is a representation that organizes the cognitive- and content-specific information into a structured representation of how the content specialist expects that examinees will think about and solve problems. Recently, Gierl and Lai (2016) proposed the *key features* cognitive model for AIG. With this model, item generation is guided by the relationships among the key features specified in the cognitive model. It is used when the attributes or features of a task are systematically combined to produce meaningful outcomes across the item feature set. The use of constraint programming in step 3 of the AIG process ensures that the relationships among the features yield meaningful items. The key features cognitive model is most suitable

for measuring the examinees' ability to assemble and apply key features within a domain as well as to solve problems using these key features.

Step 2: Create Item Models

In step 2, an item model is developed to specify where the content from the cognitive model must be placed to generate new items. An item model is a template that specifies the features in an item that can be manipulated to generate new items. Item models (LaDuca, Staples, Templeton, & Holzman, 1986) specify which parts of the assessment task can be manipulated for item generation. For a selected-response item type, it includes the stem, the options, and the auxiliary information. The stem is the part of an item which formulates context, content, and/or the question the examinee is required to answer. The options contain the alternative answers with one correct option and one or more incorrect options or distractors. Auxiliary information includes any additional material, in either the stem or option, required to generate an item, including digital media such as text, images, tables, diagrams, sound, and/or video. The stem and options can be divided further into elements. These elements are denoted as non-numeric values (i.e., strings) and numeric values (i.e., integers). By systematically manipulating the elements, many items can be generated from one item model.

Step 3: Generate Test Items Using Computer Technology

In step 3, computer algorithms place the cognitive model content specified in step 1 into the item model developed in step 2. Different types of software have been written to generate test items (e.g., Gütl et al., 2011; Higgins, 2007; Higgins et al., 2005; Singley & Bennett, 2002). Gierl, Zhou, and Alves (2008) introduced and demonstrated the use of the computer program IGOR (which is the acronym for **Item GeneratOR**) for template-based AIG. IGOR is a JAVA-based program designed to assemble test items using the items models from all combinations of elements specified in the cognitive model. Once the content is specified in step 1 and the template is created in step 2, IGOR systematically places the content into the template to produce new items as part of step 3. IGOR has been used to generate items in the content areas of mathematics, science, social studies, architecture, logical reasoning, dentistry, nursing, medical education, business management, and non-verbal reasoning.

Generating Distractors for Selected-Response Items

For the selected-response format, items must not only include a stem with a corresponding correct option, but also include a set of incorrect options or distractors. These incorrect options are typically designed from a list of plausible but incorrect alternatives linked to misconceptions or errors in thinking, reasoning, and problem solving. Using a traditional item development approach, a set of distractors are created by a content specialist that is specific to each item. But because AIG produces hundreds of items, an alternative approach is needed to create a correspondingly large number of plausible but erroneous distractors.

Three different methods can be used to generate distractors. The first method for generating distractors is often employed when the elements manipulated as part of the item generation process are first specified. Recall, elements are the variables identified by content specialist and then manipulated using computer algorithms to produce new items. A distractor can be specified as an element that contains content that is related to the correct option but still yields an incorrect response. To identify the content for this element, content specialists identify a list of plausible but incorrect options that are appropriate

for all possible items generated with a given item model. Then, distractors are randomly selected from this pool of plausible but erroneous content and added to each generated item. Hence, this method is called the *distractor pool method with random selection*. It is based on the assumption that a pool of plausible distractors can be created. A sample of these plausible distractors are selected at random to complete the item generation process. The strength of this method is its simplicity. This method can yield large numbers of distractors. The weakness of this method resides with the two strong assumptions required to use this approach. First, it must be assumed that all pooled distractors are equally plausible for all generated items. Equal plausibility is a strong and, in many cases, restrictive assumptions. Second, there is little reasoning to guide how distractors are paired with the correct option because pairing is achieved with random assignment. The distractor pool method with random selection is most appropriate for case-specific item generation, where a well-defined set of distractors are known to be plausible across a large number of the generated item.

To improve the plausibility of the distractors, rules and rationales that yield errors or misconceptions can be used to create distractors. Distractor rationales are short description provided by the content specialist to ensure that the reasoning which underlies each option is explicitly stated. When rationales are available, distractors can be systematically generated such that each distractor matches with the rationale. Hence, this approach is called the *systematic generation with rationales method*. It is based on the assumption that algorithms, rules, and procedures can first be articulated by content specialists and then used to create plausible but incorrect alternatives. The strength of this method is that the distractors are much more specific and, hence, plausible and appropriate, especially when compared to the previous method. There is also a precedent for this approach as systematic generation using distractor rationale has been used in quantitative- and rule-based content areas, such as mathematics and science, to produce incorrect options (Haladyna & Rodriguez, 2013). This method also has some weaknesses. For instance, plausible but incorrect rationales must first be created for each option by the content specialist. This process can be time consuming. Algorithmic or rule-based manipulations must also be permissible for every incorrect option. In some content areas and in some reasoning and problem-solving situations, generic rules or robust algorithms may not be available to guide the development of distractor rationales.

To overcome the weaknesses of the first two methods, a third method for distractor generation is also available. It is called *systematic distractor generation* (Lai, Gierl, DeChamplain, & Boulais, 2015). This method is closely linked to the cognitive modeling approach to AIG. Recall that to generate an item stem and correct option, specific information must be collected in the form of a cognitive model (i.e., step 1 in the three-step AIG process). The systematic distractor generation method also involves specifying information related to errors and misconceptions in the form of a cognitive model in order to generate plausible but incorrect options. The process of modeling incorrect options is more complex compared to modeling the correct option because the item stem is constantly changing in a generative item development system. As a result, the small number of constraints required to ensure that information presented in the stem yields a correct response must be counterbalanced with a much larger number of constraints required to ensure the information presented in the incorrect options is erroneous but plausible. Also, more than one incorrect option is required for a selected-response item. Typically, three, sometimes four, incorrect options must be produced for each generated item. Systematic distractor generation has many strengths. For example, it can be used in diverse testing situations and across many content areas because of its generality. It is also an adaptive method because distractors are selected conditionally using the associate information in the stem and the correct option. Finally, the features that lead to the correct and incorrect options are explicitly identified. This method also has weaknesses. Systematic distractor generation requires that specific information be collected for each distractor. Because selected-response

items contain two or more incorrect options, this specific information is required for each item in order to model the distractors. Currently, it is a time-consuming method requiring data collection from content specialists. Recent developments from Shin, Guo and Gierl (2019) demonstrated a topic modeling approach to automate the process described above to complement the generation of distractors. In this approach, content in biology is first clustered into various topics through topic modelling, then topics distances are used to determine the selection of distractors. However, a wealth of data is required to draw upon the generation process.

An Example From the Medical Health Sciences

To illustrate the three-step approach to AIG, an example from the medical health sciences is presented. This example is drawn from the content area of general surgery where the examinee is required to diagnosis problems that could arise from a serious abdominal injury. This example uses a key features cognitive model with systematic distractor generation.

In step 1, a cognitive model for AIG is created. The model in this example was created inductively by asking two 3rd year surgical residents to identify and describe the information that would be used by a surgeon to solve two serious medical problems (i.e., splenic rupture and Grade 1 liver laceration) related to abdominal injury. Three types of information are specified in the cognitive model for AIG. This information is presented as separate panels in Figure 1. The top panel identifies the main concept or problem and its associated scenarios. In this example, the problem is abdominal injury. Two associated scenarios are splenic rupture (SR) and Grade 1 liver laceration (LL). The middle panel specifies the relevant sources of information presented with the problem. In this example, three sources of information were presented: History, physical examination, and laboratory results. The bottom panel highlights the salient features, which includes the elements and constraints. The first component for a feature is the element. Elements contain content specific to each feature that can be manipulated for item generation. The second component for a feature is the constraint. Constraints serve as restrictions that must be applied during the generation process to ensure that content in the elements are combined in a meaningful way so useful items can be generated. For the Figure 1 example, five features (i.e., type of accident, hemodynamics, side, air entry, and Foley output) were identified across the three sources of information. Each feature specifies the elements and constraints. For instance, the type of accident feature has three elements, low speed, high speed, and motorcycle. These elements contain constraints. For example, splenic rupture is only related to the motorcycle accident (i.e., SR: Motorcycle) whereas the low and high speed accidents are related to the Grade 1 liver laceration (i.e., LL: Low, High).

In step 2, the item model is created (see Table 1). The item model contains the template that will be used to generate test items. It also specifies the elements for the features. Five features are included. The Type of Accident feature has three elements. The remaining four features—Hemodynamics, Side, Air Entry, Foley Output—all contain two elements. Taken together Figure 1 and Table 1 describe the content combinations required to produce the correct option in the cognitive model. Splenic rupture is the correct option, for example, when the elements are: motorcycle accident at highway speeds (Type of Accident), blood pressure is 75/35 and heart rate is 140 (Hemodynamics), left side (Side), good air entry and a large distended abdomen with guarding (Air Entry), and 100cc of bloody urine (Foley Output).

The same logic is also used to produce the incorrect options using the systematic distractor generation method. Distractor 3 is diaphragmatic rupture. This diagnosis shares some, but not all, of the elements with splenic rupture. For instance, a diaphragmatic rupture can be associated with the elements motor vehicle accident at highway speeds (Type of Accident), blood pressure is 75/35 and heart rate is

140 (Hemodynamics), and 100cc of bloody urine (Foley Output). But a diaphragmatic rupture is not associated with pain on either the left or the right side (Side) and does not necessarily display physical examination results related to air entry and abdominal pain (Air Entry), as presented in the cognitive or item models. As a result, diaphragmatic rupture is a plausible but erroneous option because it shares some but not all of the features related to splenic rupture. The same logic used to code the elements in diaphragmatic rupture is also used to code pneumothorax, cardiac tamponade, and aortic rupture in order to produce a cognitive model for the incorrect options. Then, an incorrect option is selected from this distractor model for inclusion in the generated item whenever it shares some but not all of the elements with the correct option.

Figure 1. An abdominal injury cognitive model

In step 3, IGOR assembles the content specified in an item model, subject to elements and constraints articulated in the cognitive model for both the correct and incorrect options. Iterations are conducted in IGOR to assemble all possible combinations of elements and options, subject to the constraints. In the current example, IGOR generated 62 abdominal injury items. The model used in this example is comparatively small and is provided for illustrative purposes only in our chapter. Item generation in operational testing programs typically include 5-7 different features per model where each feature has 2-10 different elements thereby producing much larger numbers of items.

Table 1. A item model for generating abdominal injury test items.

<i>Stem</i>	A 25-year-old male is involved in a [Type of Accident]. Emergency Medical Services resuscitates him with 2L crystalloid and transports him to your tertiary centre. When he arrives his [Hemodynamics]. He has a Glasgow Coma Scale score of 14. He is complaining of lower-rib pain on his [Side]. On examination, he has [Air Entry]. [Foley Output] . What is the most likely diagnosis?
<i>Elements</i>	Type of Accident: 1: highway speed roll over 2: bicycle accident where he hits a barricade 3: motorcycle accident at highway speeds Hemodynamics: 1: blood pressure is 75/35 and his heart rate is 140 2: blood pressure is 140/90 and his heart rate is 90 Side: 1: left side 2: right side Air Entry: 1: good air entry and a large distended abdomen with guarding 2: good air entry, mildly tender abdomen, and no guarding Foley Output: 1: A foley catheter emits 100cc of bloody urine 2: A foley catheter emits 600cc of urine
<i>Options</i>	1: Splenic rupture 2: Grade 1 liver laceration 3: Diaphragmatic rupture 4: Pneumothorax 5: Cardiac tamponade 6: Aortic rupture 7: Epidural hematoma
<i>Key</i>	

FUTURE RESEARCH DIRECTIONS

Item generation is currently attracting great interest from a diverse audience beyond the testing development experts. Although efforts are being made across computing science, psychometrics, and other content experts, three directions of research can be expected in the near future: the expansion of the AIG method, the development in different content areas, and the evaluation of the generation process. In expanding the AIG method, an area of research that is widely sought after in item generation is the integration of calibrated item parameters with the generated items. If items can be generated with their statistical properties, then it can mitigate the issue of field testing and quality control. Although statistical models exist on how item parameters can be generated (Lai & Gierl, 2012; Cho et al., 2014; Sinharay & Johnson, 2013; Graf & Fife, 2013), few studies were able robustly deploy a model that can accurately match difficulty estimation to generated items. A challenge in this area often lie with what

information is used to inform parameter estimation. Chen et al., (2019) continued this line of research and was only able to estimate difficulty variations for 5% of their generated items. Efforts on calibrated item generation will likely continue in the future as statistical estimation of generated item properties is information highly desired.

In developing content in different content areas, methods are now being developed for their own context. Mindyarto, Nugroho & Linuwih (2018) using the item modeling method to create physics testlet items. Gunabushanam et al. (2019) was able to follow the item modeling method to create items in the context of radiology. Growth in unsuspecting areas are also bringing the use of new technologies. Von Davier (2018) used a bank of over 3000 items in a personality inventory as basis for generation through a neural network to provide basis. Segments are reassembled based on learned patterns from neural network to assemble into an item. Leo et al. (2019) followed an ontological approach and generated over 3 million items through assembling and querying an existing medical ontology to generate items based on the relationships as defined in the ontology. In sum, as the content areas continue to grow, more attempts will be made in expanding the item generation method integrate natural language processing techniques.

In the evaluation of generative outcomes, studies on its feasibility and practicality are beginning to take place. Embretson and Kingston (2018) evaluated the efficacy in the production of items in the area of mathematics. Their study demonstrated feasibility in the production of items, but highlighted challenges in adopting item generation with either test development practices such as field testing and parameter estimation. One notable advantage of generating test items is the scalability of the approach. However, the efforts required to scale the production of an item model also requires greater investment of cost than written items. To evaluate the return-on-investment of item generation as an approach, Kosh et al. (2018) conducted a cost analysis on item generation and found that the comparatively larger upfront cost of item generation is off-set if there is a demand for greater than 173 items per content area. In this analysis, they have accounted for the up-front cost of generation, survival rate of items in the review process, and time required for model development. Finally, Attali (2018) evaluated a broad deployment of generated items in a low-stake learning companion context. Following closely to the concept of item model, Attali evaluated their deployment of generated items for 6000 students as practice questions. With different use case driving the need for item generation, we suspect evaluation of AIG as a method in its effectiveness and adoption will continue to be needed to convince skeptics in the near future.

CONCLUSION

As the importance of technology continues to increase, countries require skilled workers who can produce new ideas, products, and services. The ability to create these outcomes will be determined by the effectiveness of our educational programs. Education provides students with the knowledge and skills required to think, reason, communicate, and collaborate in a world that is increasingly shaped by knowledge services, information, and communication technologies. Computerized testing will foster the development of this highly skilled workforce by helping students acquire these essential skills. Computers allow educators to administer tests more frequently so students can receive specific continuous feedback as they develop their skills. But when tests are given more frequently, a constant supply of test items is needed. Automatic item generation is a rapidly evolving research area where cognitive and psychometric theories are used to constantly produce tests that contain items that are generated with computer technology. The purpose of this chapter was to describe and illustrate a template-based method for generating

test items to address the challenging problem of rapidly and economically producing large numbers of high-quality, content-specific, test items required to support computerized testing.

KEY TERMS AND DEFINITIONS

Automatic Item Generation: A process of using item models to generate test items with the aid of computer technology.

Cognitive Model: A representation that highlights the knowledge, skills, problem-solving processes and/or content an examinee requires to answer test items.

Distractor Pool Method with Random Selection: A method for creating distractors when the distractors created from a list and then the list is used to randomly select plausible but erroneous content for each generated item.

Elements: Variables in the item model that can be modified to create new test items.

Item Model: A template that highlights the features in an item that must be manipulated to generate new items.

Key Features Cognitive Model: A model used to guide item generation based on the relationships among the key features specified in the cognitive model, which include the attributes or features of a task are systematically combined to produce meaningful outcomes across the item feature set.

Systematic Distractor Generation: A method for generating distractors where specific information related to errors and misconceptions is used to create plausible but incorrect options.

Systematic Generation with Rationales Method: A method to systematically create distractors when rationales are used to produce a list of incorrect options.

INTRODUCTION

The rapid acceleration of human-centered and technology-oriented advancements in a multitude of industries and fields means that most **organizations** could greatly benefit from an expansion of coverage into all aspects of **organizational** research, allowing for a greater breadth and range of content. In a chapter on transdisciplinary approaches to action research for Information and Communication Technologies for Development (ICT4D), Goosen (2018c, p. 97) further recommended that researchers “ought to try out the theories they propose together with practitioners in real-world situations and with real **organizations**, towards making academic research relevant.”

The purpose of this chapter is therefore to offer insights into key topics, such as **organizational structure, strategic leadership, information technology management, and analytics**, among others, especially as applicable in the emerging areas of ICT4D and Massive(ly) Open Online Courses (MOOCs). This chapter will be comprised of content that highlights authoritative research results, directed at the proposed target audience of this book. “That is why students, professors, and universities” could be interested (Abbakumov, Desmet, & Van den Noortgate, 2019, p. 332), together with e-learners, teachers and managers at e-schools in South Africa (Goosen & Van der Merwe, 2015), as well as researchers, educators, students, professionals, and knowledge seekers from all around the world, as these pertain to all aspects of **organizational growth and development**, specifically discussed in the context of a MOOC entitled ‘Ethical Information and Communication Technologies for Development Solutions’.

“With e-learning technologies evolving and expanding at high rates, organizations and institutions around the world are integrating” MOOCs and other Open Educational Resources (OERs) in order to address problems, especially for “Open Education in the Global South” (Zhang, Bonk, Reeves, & Reynolds, 2019). In their guest editorial on initiating the debate regarding perspectives on teaching, learning and assessment in Open Distance e-Learning (ODEL) contexts, Prinsloo and Coetzee (2013, p. 1355) indicated that there are many **problems** “facing higher education institutions, such as changes in funding regimes, the impact of technologies, changing student profiles and the impact of the economic downturn, to mention but a few.” According to Subotzky and Prinsloo (2011), the **problems** and imperatives related to enhancing student support for retention and success at Higher Education Institutions (HEIs) in particularly South Africa are formidable, where success rates and retention are notoriously poor. Examples of conference papers, which detailed such issues include Goosen (2014), who aimed to investigate effective teaching and meaningful learning to address the **problems** of Information and Communication Technology (ICT) education in an Open and Distance e-Learning context, and Goosen

DOI: 10.4018/978-1-7998-3473-1.ch020

(2015c), on assessment to address the **problems** of effective teaching and meaningful learning in an ICT4D MOOC.

The chapter represents significant innovative work by closing gaps regarding research and “sharing of teaching practices that empower educators to benefit from the best ideas of their colleagues” (Cape Town Open Education Declaration, 2007). Further significance of the chapter lies in presenting an original piece of work contributing to academic debate under the theme of scholarship of teaching and learning in higher education (Subotzky & Prinsloo, 2011). Potentially useful content, with interest value for the intended audience, particularly facilitators, include examples of practice relating to the themes of student support in ODeL for increasing retention and success in courses with massive participation at higher institutions of learning (Firmin, Schiorring, Whitmer, Willett, Collins and Sujitparapitaya, 2014; Jona & Naidu, 2014; Subotzky & Prinsloo, 2011), the assessment of students and using Information Communication Technologies (ICTs) to facilitate teaching and learning (Libbrecht & Goosen, 2015).

“In recent years there has been a significant growth in the number of online courses known as MOOCs available” (Liyanagunawardena, Lundqvist, Mitchell, Warburton, & Williams, 2019). According to Bates (2014), the **organization** and management of social learning on such a massive scale, without the loss of potential advantages related to collaborating at such a scale, is still a major **problem** remaining to be adequately addressed. Like that of Fischer (2014), this chapter not only reports on collected data regarding existing practices, but also investigates the advantages and disadvantages of different design choices, in order to help identify the e-learning practices worth preserving.

Although much can be deduced by relying more on student and/or lecturer feelings and perceptions, there is a need to represent “perspectives on MOOCs from outside Western contexts”, based on actual cases (Bates, 2014, p. 147).

Baggaley (2014b) agreed that reporting on North American MOOC practices does not provide any evidence regarding the transferability of these to other regions, where some students are literally studying “in a village in Africa”, as had somewhat contemplatively been expressed by Fischer (2014, p. 151). In a slightly earlier reflection for the Distance Education journal (Baggaley, 2013), regarding the rapid rise of MOOCs, Baggaley (2014a) also indicated that MOOC evaluations, which are now emerging, are finding that claims regarding courses, which are supposed to be appropriate for worldwide adoption, are groundless. Fischer (2014) agreed that the particular **problems** related to courses that reach beyond individual countries’ borders need to be carefully considered.

Although indications are that established constructivist or instructionist approaches to pedagogy are usually adopted in relation to the curriculum development, pedagogy and assessment of MOOCs, questions are also asked to make the underlying assumptions and theory informing the chapter evident (Knox, 2014).

A diversity of educational research methodologies implemented regarding MOOCs included heuristics, data and learning analytics, utilizing a case study (Firmin, et al., 2014), using user statistics and survey data to examine students’ experiences, and reporting on studies investigating co-located MOOC study groups, using quasi-experimental comparisons (Li, et al., 2014).

This chapter discusses analysis results on survey data about the context of this MOOC, to discover lessons learned from the affordances and acceptance of established and emerging technologies when used regarding student support for retention and success (Diver & Martinez, 2015). Also included are results on how OERs made available online were used by educators, with the main aim of the MOOC having been growth in students’ proficiency” in such areas (Abbakumov, et al., 2019, p. 332).

It is important to identify **problems** such as those mentioned previously to the future of MOOCs (Fischer, 2014), faced regarding the scholarship of teaching and learning applied to large cohorts (Bag-

galey, 2014a), as the success of MOOCs depend on how well these are managed. Concluding remarks propose calls considering implications regarding MOOCs, including multimodal approaches to pedagogy and research in the discipline of ICTs (Baggaley, 2013).

Similar to what was done by Jona and Naidu (2014), referring to Bates (2014), this introduction has now described and summarized the general perspective of the chapter, which provides a useful point to start, in order to draw some lessons learned, based on theoretical groundings, as well as qualitative and quantitative data (Fischer, 2014). Towards this end, the objectives of the chapter will be specifically stated as being part of an investigation to establish:

- What **organizational knowledge** can be gained from an ICT4D MOOC in terms of the affordances (opportunities) presented by established and emerging technologies in growing capacities for sustainable ODeL provision?
- To what extent can **administration** lessons learnt from an ICT4D MOOC improve the acceptance by students of established and emerging technologies used for growing capacities for sustainable ODeL provision?

BACKGROUND

This section of the chapter will provide broad definitions and discussions of the topic and incorporate views of others into the discussion (in the form of a literature review), to support, refute and/or demonstrate the author's position on the topic.

Naidu (2016, p. 1) saw “openness as part of a bigger agenda incorporating many other dimensions of learning and teaching as opposed to a rather narrow focus on free and open access to educational resources”. According to Cronin and MacLaren (2018, p. 127), open education is defined “as encompassing resources, tools and practices to improve educational access, effectiveness, and equality worldwide”, while Weller, Jordan, DeVries and Rolfe (2018, p. 109) believe that the “term open education has recently been used to refer to topics such as” OERs and MOOCs. Embodying “the values and visions of openness”, Koseoglu and Bozkurt (2018, p. 455) defined Open Educational Practices (OEPs) as “a broad range of practices ... informed by open education initiatives”. Against the background of growing awareness of new digitally-enabled OEPs, the relationship between these and established educational modes, such as Distance Education (DE), remains unclear (Prinsloo, 2016), especially with the overlapping issues of student empowerment and/or inclusion through open practice (Czerniewicz, 2018; Hodgkinson-Williams & Arinto, 2017).

Theoretical and Conceptual Frameworks

Relating to the context as set out in the introduction to this chapter, Subotzky and Prinsloo (2011, p. 177) presented “a socio-critical model and framework” to understand, predict and enhance student support for retention and success in ODeL and “developed at the University of South Africa”. Jona and Naidu (2014) emphasized the importance of agreeing on a shared vocabulary for discussing and debating questions regarding the theoretical and conceptual frameworks underpinning pedagogical approaches instantiated in MOOCs. In response, Knox (2014) indicated that established **constructivist** or instructionist approaches to pedagogy are usually adopted in relation to the curriculum development and assessment of MOOCs.

In this same context, Kop and Hill (2008), however, asked whether connectivism was a learning theory for the future, or vestige of the past?

Literature Review

The article by Goosen and Van Heerden (2013), according to Prinsloo and Coetzee (2013, p. 1360), shared “findings regarding the impact of the introduction of project-based learning and assessment”, which showed that these “increased not only the effectiveness of the teaching, but also students’ self-confidence”, as it can “be used effectively for assisting in learning academic areas” (Goosen, 2019b, p. 89) for an undergraduate Computer Science course in an ODeL context.

Scholarship of Teaching and Learning

Shulman (2000) asked why there should be a Scholarship of Teaching and Learning (SoTL), while the question from Kreber (2007) was what the scholarship of teaching and learning as an authentic practice was really all about?

According to Prinsloo, Slade and Galpin (2012, p. 133), both the University of South Africa and the Open University encouraged “the scholarship of teaching and learning to increase evidence-based approaches to interventions aimed at improving student retention and success.” In this same milieu, Pintrich and Zusho (2007) provided an evidence-based perspective on student motivation and self-regulated learning in the college classroom, against the background of the scholarship of teaching and learning in higher education.

Prinsloo and Coetzee (2013, p. 1357) added that, against “the changing landscape of higher and distance education, the possible foci in” fields related to ODeL research are diverse, including “the need to expand the scholarship of teaching and learning to provide evidence-informed and value-based foundations from which to shape teaching, learning,” student support and assessment practices. Since the latter authors (Prinsloo & Coetzee, Initiating the debate: Perspectives on teaching, learning and assessment in ODL contexts, 2013, p. 1363) indicated that the different **problems** “inherent in the nexus between the scholarship of teaching, learning and assessment and disciplinary research” need to be considered, Huber and Morreale (2002) explored common ground regarding disciplinary styles in the scholarship of teaching and learning.

While Hatch (2005) looked at taking the development of the scholarship of teaching and learning into the classroom, Richlin and Cox (2004) investigated new directions in terms of developing scholarly teaching and the scholarship of teaching and learning through faculty learning communities. In the same kind of scenarios, in their capacities as faculty luncheon speakers, in Dawson, et al. (2015):

- Dawson examined assessment alignment as a process for program evaluation,
- Ritchie carried out a quantitative investigation into collaborative testing to improve learning,
- Newton used case-based learning in undergraduate Biochemistry education, regarding design, implementation, and pedagogical outcomes,
- Wolstenholme and Aspenlieder studied teaching evaluations and SoTL for continuous improvement,
- Yankulov considered peer review, writing and presenting in undergraduate courses, in terms of how teaching innovation and teaching/learning research can be united,
- Jacobs researched how to collect, analyze, and present qualitative data,
- Graether investigated quantitative and qualitative analysis of courses and students, and finally,

- Bettger explored SoTL opportunities arising from the design of a ‘Biological Concepts of Health’ course.

Learning Analytics

In the proceedings of the first international conference on learning analytics and knowledge, Fournier, Kop and Sitlia (2011) commented on the value of learning analytics to networking in a personal environment.

Prinsloo, Slade and Galpin (2012, p. 131) pointed out that despite all the research on student “retention and success since the first conceptual mappings of” student success, “there have not been equal impacts on the rates of both” student success and retention. To realize “the potential of learning analytics” towards impact, the **problems**, paradoxes and opportunities related to learning analytics for mega ODeL institutions need to be appreciated.

According to Willis, Slade and Prinsloo (2016, p. 881), learning analytics’ growth as a means for improving learning outcomes means that student data is being collected, analyzed “and applied in previously unforeseen ways.” The latter authors therefore derived a typology from a cross-continental, cross-institutional perspective, as Bolton, Goosen and Kritzinger (2016, p. 1) are of the opinion that the influence of such social change needs to be “discussed, highlighting the new requirements” with regard to the ethical oversight of student data in learning analytics.

MASSIVE OPEN ONLINE COURSES

“In the field of education,” MOOCs “have raised remarkable attention throughout the last decade” (Otto, et al., 2019, p. 12). MOOCs represent “an instructional approach that permits hundreds of thousands of students to access online courses anywhere around the world and typically free of charge” (Weinhardt & Sitzmann, 2019, p. 218). “The large numbers that enrolled, coupled with the unprecedented reach through the internet” (Oakley & Sejnowski, 2019, p. 1), also means that MOOCs “allow learning to take place anytime” (Wong, et al., 2019, p. 356).

The fact that MOOCs tend to not be based on instructional principles that are widely accepted was lamented by Baggaley (2014a), and as this same author indicated that studies evaluating early ‘connectivist MOOCs’ have indicated **pedagogical** deficiencies in these, it would be essential to consider this as well.

Similar to what was reported with regard to one of the very first MOOCs, the author is of the opinion that the particular course reported on in this chapter has a solid **pedagogical** approach and includes the use of open educational resources (Baggaley, 2013; Fischer, 2014; Jona & Naidu, 2014).

Although designing MOOCs is undergoing rapid curriculum development with regard to pedagogy and assessment, a lot has already been established about ODeL, which needs careful application and supervision when instructionally designing MOOCs (Bates, 2014)

– one finding in this regard is that e-learners, teachers and managers at e-schools in South Africa (Goosen & Van der Merwe, 2015), as well as students at HEIs, want e-learning as part of their education (Goosen, 2016).

According to Diver and Martinez (2015, p. 5), it is not correct considering MOOCs as wholly different entities, “outside and apart from other types of” distance education and e-learning environments. Baggaley (2013, p. 369) agreed that very little about MOOCs “is actually new, and plenty of lessons are available about how” these can be implemented; Jona and Naidu (2014, p. 142) therefore asked what lessons from existing e-learning “and mainstream distance education research” can contribute, and what

the unique educational technologies for growing innovation are, which support the design, implementation, analysis, delivery and/or evaluation of MOOCs in the 21st century (Goosen, 2015a). One example of such research, on excellence in e-learning course design, was reported on by Goosen (2015b).

The approach followed had a team including individuals “trained in instructional **design**, the learning sciences, educational technology, course design or other educational specialties to help with the design of their courses” (Baggaley, 2013, p. 373, quoting Holden). The online development and curriculum design of the course was informed by a contextual analysis, liaison with industry and/or professional bodies and other relevant stakeholders, and/or relevant market research, including applicable quality assurance criteria in terms of the planning process.

When choosing the ‘best’ elements towards developing a MOOC, as discussed in the previous paragraph (Goosen, Mentz, & Nieuwoudt, 2007), research like that of Van Heerden and Goosen (2012), on using vodcasts to teach in an ODL environment can be born in mind. Such elements were augmented “by innovative technological developments such as delivering content” by using readings, **problems**, assignments and a portfolio, as well as enrichment components, such as peer-to-peer learning support, to provide scalability to large audiences in terms of technology perspectives, including platforms supporting the sizeable number of students being added to these e-learning environments – these also fostered learning through conversations, activities and participatory settings (Fischer, 2014, p. 153). Since Li et al. (2014) suggested that MOOC students prefer studying in groups, social facilitation within such groups could make learning difficult concepts a more pleasant experience. e-Learning discussion forums for affording communication among participants, and supporting the importance of self-directed, **problem**-based and active learning, as well as fostering collaboration amongst students, and interactivity for “providing **feedback** (e.g., with automatic grading)”, were therefore also implemented (Fischer, 2014, p. 153). Students are teaching each other (Baggaley, 2013) and taking responsibility to digest the information being presented to them, to discuss it with other students (Baggaley, 2014b).

Since, however, Baggaley (2013) reported on the huge amount of information available in these discussion forums, this same author (Baggaley, 2014b, referring to Knox) warned that numerous MOOC students are crushed by this peer-to-peer approach. The author agrees with Fischer (2014, p. 152) that the students can be disorientated by the “volume of ideas and comments”, while Knox (2014, p. 169) pointed out that “MOOCs can provoke anxiety about presence and orientation in relation to” these large-scale activities.

According to Baggaley (2013, quoting Carter), lecturers and policy-makers are further facing the increased costs of infrastructure and of teaching an increased number of students using fewer resources (Fischer, 2014). Firmin et al. (2014) pointed out that HEIs therefore increasingly consider the integration of MOOCs into their overall curriculum and course activities by including support services, with enrolment sizes being similar.

“The large audience base of” MOOCs is challenging pedagogical practices (Li, et al., 2014, p. 217). It is impossible for a single lecturer to handle such massive student numbers (Baggaley, 2014a). With regard to curriculum development, pedagogy, assessment, as well as the need for the lecturer “to provide the students with **feedback**” (Baggaley, 2013, p. 369), one “prominent **problem** is the elimination of the traditional **interaction** between” lecturers and students (Li, et al., 2014, p. 217), as “learning **feedback** cannot be obtained directly from the” lecturer. Fischer (2014, p. 153) indicated that “an important question to ask is: Could the technology used in distance education ever become good enough to mimic the ease and richness of **interaction**” seen in face-to-face settings? The figure of the lecturer is “often considered indispensable, calling into question MOOC designs that too quickly assume the” lecturer “to be merely ‘a fellow node’ in the network ..., or even a role that is increasingly obsolete” (Knox, 2014, p. 172).

These **problems** can be addressed through the establishment and support of curator roles for **organizing** the potentially large information spaces, who were called Teaching Assistants (**TAs**) in the course discussed in this chapter. As opposed to the situations described by Baggaley (2014b), which dispensed with teaching support, and in another instance, where courses were unsupervised, lecturers played no role in appointing and monitoring of the teaching assistants, nor provided these lecturers with any training (Baggaley, 2013). Wong et al. (2019, p. 356) also reported a situation “with little external monitoring by” lecturers.

While learning has taken place in both open and distance contexts, MOOCs have increased the size of student enrolments (Baggaley, 2014b) to situations where participation numbers “in the tens of thousands” (Knox, 2014, p. 164) “of students in a single course” (Baggaley, 2013, p. 368). The large enrolment numbers associated with MOOCs underscores the importance of engaging in e-learning student support for retention and success with regard to educational activities (Firmin, et al., 2014), which compelled Diver and Martinez (2015) to investigate **issues** related to MOOC dropout, with high non-completion rates in MOOCs also being reported (Jona & Naidu, 2014).

Marshall (2014, p. 250) indicated that there are significant “research **ethics** concerns arising from” various initiatives around the “analytical and other work being done by academics and” HEIs, regarding specifically MOOCs. According to Jona and Naidu (2014), the latter essay by Marshall (2014) explored the **ethical** considerations relating to this new educational approach and research findings, which “should be used to inform” and must serve to guide the “thoughts and approaches to MOOCs” (Diver & Martinez, 2015, p. 6) in terms of the decision-making of key stakeholders, including students, individual faculty members and/or higher education institutions’ online support services, coordinators, leaders and **administrators**, who consider the implementation of MOOCs in their organizations (Firmin, et al., 2014). Similarly, Jona and Naidu (2014, referring to Baggaley) also raised concerns that many lecturers and distance education researchers share: Baggaley (2014b, p. 162) is of the opinion that “the **ethical** approach taken by Marshall (2014) may ultimately pose the unarguable” **problem** that decision-makers cannot ignore.

According to Goosen (2018b, p. 19), it “is important to indicate whether the researcher has received permission to conduct research from the relevant authorities, where research involves the utilization of space, data and/or facilities at other institutions and/or **organizations**.” Both Baggaley (2014b) and Jona and Naidu (2014, p. 143) therefore encouraged all those HEIs who participate in the development, **administration** and study of “MOOCs to pause and consider the many important implications of this new technology and” the **ethics** of these and associated practices and policies. In this regard, the chapter by Goosen (2018a) discussed ethical information and communication technologies for development solutions in terms of research integrity for MOOCs.

RESEARCH METHODOLOGY

The diversity of research methodologies, which had previously been implemented relating to MOOCs, have included:

- Okada, Scott and Mendonca (2015) using a case study on effective web videoconferencing for proctoring online oral exams at scale in Brazil;
- Greenland and Moore (2014) with a preliminary case study investigating patterns of student enrolment and attrition in Australian open access online education;

- While Firmin, et al. (2014) utilized a case study on using MOOCs for conventional college coursework in a distance education context,
- the chapter by Goosen (2019a) used a case study of a MOOC to provide details on technology-supported teaching and research methods for educators.

Similar to the situation described by Rodriguez (2013, p. 68), the collection of “qualitative and quantitative data through” surveys given to participants towards “the end of the courses” reported on in this chapter also “concentrated on the **design** of the courses, statistics and content”, and were likewise used “to determine general demographic information ... and participant satisfaction with the courses.”

SOLUTIONS AND RECOMMENDATIONS

Unfortunately, the commentary by Bates (2014) did not include any findings. The aim of this section of the chapter will, however, be “to categorize and describe different types” of students in the MOOC by means of some of the quantitative findings from the research mentioned in this chapter (Luna, Fardoun, Padillo, Romero, & Ventura, 2019, p. 1).

Coughlan and Perryman (2015, p. 181) reported on a MOOC called *Physiotherapy Management of Spinal Cord Injuries*. Like the afore-mentioned, the MOOC reported on in this chapter runs in each of two semesters per year and attracted, on average, almost 16,000 registrants per semester for the period referred to in this chapter, and like Goosen (2016) and Wong et al. (2019), will be reporting on characteristically, highly diverse groups of students in the samples from 30 countries.

Fischer (2014, p. 150) also reported that for the course reported on in that paper, “on average only about 50% of those who registered for a course ever viewed the” learning materials. Table 2 shows that up to 84% of students not only viewed the learning materials, but, in fact, used the functions on the institutional learning management system (myUNISA) for this course to download learning materials.

As online courses, MOOCs have notoriously high attrition (Mongkhonvanit, Kanopka, & Lang, 2019). Also reporting on the low completion rates for MOOCs, Fischer (2014, p. 150) indicated that “only about 4% completed the courses”, while Baggaley (2013, p. 372) reported “that only 14% of the participants completed the course”. In sharp contrast, the MOOC reported on in this chapter has shown completion rates (number of students registered at the time of mark sign-off divided by number of students who completed the final portfolio) as high as 89% for the first semester of 2014 (Goosen, 2018a). The percentage of students who pass the course has also been standing at a constant of 84% since the second semester of 2014.

Recommendations

With regard to methodological issues, Boucher and Piderit (2017, p. 161) **recommended** action research as “a commonly used method for the demonstration of the scholarship of teaching and learning”.

According to Fischer (2014, p. 154), the use of human tutoring and/or assignment marking of individual students and teaching assistants to support the discussions towards operating more successfully, and to support students experiencing **problems** “with content and/or technical issues” are **recommended**.

Fischer (2014) additionally **recommended** that **future** research needed to be conducted for exploring a range of **issues** around open questions, such as whether MOOCs are able to enculturate the building of communities and feelings amongst the students taking a course.

FUTURE RESEARCH DIRECTIONS

This section of the chapter will discuss **future** and emerging trends and provide insight about the future of the encyclopedia's theme, of **organizational** knowledge, **administration** and technologies, from the perspective of the chapter focus on **organizational knowledge** and **administration lessons** from an ICT4D MOOC. The viability of **paradigms**, models, implementation issues of proposed programs, etc., may also be included in this section. Finally, this section of the chapter will suggest future research opportunities within the domain of the topic.

In the context of information and knowledge management, Thomas (2011) pointed to cloud computing as a potential **paradigm** for practicing the scholarship of teaching and learning. In this regard, Shulman (2001) believed approaches to the scholarship of teaching and learning are opening lines towards inventing the **future**.

Despite Baggaley (2013) warning against the uncritical hype, which often accompanies the use of new educational technologies, supporters of MOOCs have been able to generate enthusiasm and excitement worldwide (Fischer, 2014). As such, MOOCs present potentially exciting possibilities and opportunities to explore innovative, multi-dimensional aspects of the use of technology for openness in the ever-changing and expanding world towards embracing the **future** of ODeL. These also relate to theories, which drive practice (Jona & Naidu, 2014), and empirically investigation of the affordances and acceptance by students of both established and especially emerging technologies in growing capacities for sustainable ODeL provision - especially in South Africa and regarding the first-year experience (Marshall, 2014).

The research team in the article by Firmin, et al. (2014) suggested that **future** investigations should be conducted into the roles, which e-learning and other student support efforts can play in accelerating persistent efforts towards improving outcomes for the different student populations, who are enrolled in MOOCs. The context presented by the confluence of MOOCs, e-learning and distance education, more generally, can represent another important component (Fischer, 2014). Furthermore, according to Bates (2014), one of the more critical areas for **future** research and development is that the MOOC community still lack methods and designs for making progress towards the creation of the best environments, which properly support participants.

Jona and Naidu (2014) called for **future** exploration of promising new insights towards advancing the understanding and practice in terms of fitting the learning and teaching needs of 21st century MOOCs (Goosen, 2015a), included establishing common grounds for a shared understanding of the incorporation of locally relevant issues and needs (Fischer, 2014). Together with addressing pedagogical concerns, both more recent and established in nature, these offers yet another avenue of exploration, which can affect the framing of informed discussions, academic debate, and decisions regarding MOOCs and e-learning course design that are taking place (Diver and Martinez, 2015).

Fischer (2014, p. 151) pointed out the importance of identifying research **problems** to the **future** of MOOCs, with the success of MOOCs depending on how well these are managed regarding common **problems** faced regarding the scholarship of teaching and learning applied to large cohorts (Baggaley, 2014a). These **problems** could include “whether students can learn what they want and when they want it” (Fischer, 2014, p. 151), as well as providing access to individual students “that they would not have otherwise” (Fischer, 2014, p. 155) - Goosen (2018d) provided details around students’ access to an ICT4D MOOC.

According to Diver and Martinez (2015, p. 21), MOOCs generate tremendous amounts of data, which “can be used not only” for improving the MOOCs themselves and their associated e-learning

environments, but can also act as a reference to analyze and reflect on “past, current, and **future** MOOC developments” (Fischer, 2014, p. 149).

Bozkurt, Koseoglu and Singh (2019, p. 78) emphasized that open educational practices “as an emerging area of study” also offer “fertile ground for **future** research.”

CONCLUSION

Since Liyanagunawardena, et al. (2019) indicated that previous results have seen “a marked reduction in the clarity around the different course offerings”, this has created a research gap. This section will provide discussion of the overall coverage of the chapter and concluding remarks, which propose a call with regard to further consideration of MOOCs in terms of moving beyond individualism and self-interest towards achieving **implications** related to MOOC design, especially the **implications** for those practitioners and researchers from HEIs that have previously engaged and/or specialized in the higher education arenas of distance education.

“In order to gauge the significance of education at scale,” like that of Knox (2014, p. 164), this chapter analyzed a specific example “of massive participation derived from” e-learning and distance education, “a MOOC from the University of” South Africa. User statistics and survey data were used to illustrate this, and for the examination of “the experiences and repercussions of engaging” in educational activities “where participants number in the tens of thousands.” This was in response to the call from Baggaley (2014b, p. 162), that the consequences with regard to effectively “learning for the vast majority of participants who took” part in MOOCs need to be established.

The chapter pointed out the organizational knowledge that can be gained from an ICT4D MOOC in terms of the affordances (opportunities) presented by established and emerging technologies in growing capacities for sustainable ODeL provision, as well as administration lessons learned from creating an ICT4D MOOC to improve acceptance by students. The results showed that this MOOC is increasingly popular among students from around the world (Abbakumov, et al., 2019).

As Knox (2014, p. 173) indicated that some students “responded to massive participation in ways that can be interpreted as overload” and/or anxiety, “more work is needed within the open educational movement to consider how to work with a global audience that has significantly different experiences and beliefs about education”.

KEY TERMS AND DEFINITIONS

Connectivism: A theoretical framework for understanding learning, the latter taking place when knowledge is stimulated through a cyclical process, started when students connect to a socially networked environment to find and share new information.

ICTs for Development (ICT4D): An academic field constructed of building blocks, providing complementary perspectives from information systems, as well as development management.

Information and Communications Technologies (ICTs): Any devices used for creating and/or capturing, storing, processing, managing, as well as any dissemination/transmission/transfer and/or display of data and information by using digital means.

Massive(ly) Open Online Courses (MOOCs): MOOCs are characterized by their massive enrollment figures in terms of number of students, who have open access to the online content of these courses.

Online Learning or E-Learning: Learning that takes place via the internet, using a variety of devices to access the web.

Plagiarism: Failure to acknowledge the work of others.

Sub-Saharan Africa (SSA): Those African countries located towards the south of the Sahara Desert.

Preferences, Utility, Value–Driven Modeling, and Decision Support

INTRODUCTION

Organizational knowledge is indispensable in the process of modeling complex systems, which describe phenomena with significant human participation. A complex system is a system with the active or decisive involvement of the person in the determination of objective, description, and choice of the final decision as an element of the system itself. In the context of the system analysis, this is a “human-process”-system. This conception is reflected in the decision-making theory at the stage of determination of the system structure in the light of the main objective. At such a basic level, the needed information and knowledge are generally expressed in ordinal scale as human preferences. The chapter focuses attention on complex models and mathematically well-founded methods where the decision-maker (DM) is represented through his preference as a value or utility function, being part of the mathematical modeling process. It is a value-based design, an engineering strategy grounded on system analyses enabling multidisciplinary design optimization (Collopy & Hollingsworth, 2009).

A benefit could be to integrate the human’s preferences with machine learning. The latter focuses on a prediction that builds on known properties derived from training data. Machine learning explores the construction and learning algorithms that can learn from teaching experts and make predictions. According to some opinions, machine learning and pattern recognition can be viewed as two facets of the same problem. As a scientific field, Machine learning is an area of computer science, evolved from pattern recognition and computational learning theory (Aizerman, Braverman, & Rozonoer, 1970; Vapnik, 1998; Mandel, 2018). The decision-making is also an iterative process that includes learning as an essential part of its realization (Keeney & Raiffa, 1999). The combination of the abovementioned theories and approaches enable constructing mathematical value-based models of complex systems like

DOI: 10.4018/978-1-7998-3473-1.ch021

“human-process” and building a mathematically well-grounded control solution as a flexible, iterative mutual learning process (Pavlov & Marinov, 2017).

Value focused thinking and value-based modeling imply a mathematical paradigm applicable in diverse areas of activity (Erickson, 2002). The utility theory and the proposed approach offer an appropriate solution. The main goal is to demonstrate this unified mathematical approach, reduced to specific numerical methods, in a broad scope of applications in complex systems. The objective of the chapter is to present such a strict logical mathematical approach for value modeling and estimation of human preferences as machine learning in the process of construction of two examples of complex systems with human participation in two completely different areas of activity. The first model focuses on forestry timber production rendering an account to landscape design, social and ecological biodiversity factors. The second model concerns the classroom teaching and determining the optimal usage of active and passive resources based on information and communication technology (ICT).

BACKGROUND

A reasonable approach to the mathematical description of human beings is an analytical representation of their preferences. Preference representation as value or utility function enables value-based modeling. Value-based decision-making based on human preferences and their inclusion in complex systems is a challenge and a modern research trend simultaneously. It is the first step in the implementation of human-centered value-driven design in a decision-making process (Keeney & Raiffa, 1999). The main objective is to avoid the contradictions in human’s decisions in complex processes and to permit mathematical calculations in these fields.

The complex phenomena and the characteristics of human thinking raise uncertainty in the expressed human preferences. The mathematical approach to modeling such type of thinking and acquired information includes the theory of measurement, utility theory, theory of probability and various aspects of operational researches (Keeney & Raiffa, 1999; Clarke, 1983; Aubin, 2007). Especially promising in this direction is the stochastic approximation theory and the potential functions method. The latter, by its nature, allows machine learning and is used in various fields, including a mathematical description of perceptions (Aizerman et al, 1970; Mandel, 2018).

PREFERENCES, STOCHASTIC APPROXIMATION AND UTILITY REPRESENTATION

When the alternatives are arranged by preferences, it implies the *ordering scale*. In the case of decision-making under certainty, every DM’s choice corresponds to only one outcome (alternative x , $x \in X$). X denotes the set of alternatives, e.g. possible outcomes, provoked by the DM’s actions. Let consider a more general scheme of interaction between DM and the real world. Assuming that for every choice of the DM, there are (i , $i=1 \div n$) possible outcomes (alternatives), each of which occurs with probability p_i , where $\sum_{i=1}^n p_i = 1$. Thus, every decision corresponds to one possibility distribution (p) as an outcome.

Following the Bayesian approach, it is reasonable to maximize mathematical expectation $\sum_{i=1}^n p_i u(x_i)$ (Keeney & Raiffa, 1999; Fishburn, 1970). The function $u(x)$ is a utility function that evaluates the different

final alternatives $x \in X$. The normative (axiomatic) approach regards the conditions for the existence of utility function $u(\cdot)$ (Fishburn, 1970; Pfanzagl, 1971). X is the set of alternatives and P – a convex set of probability distributions over X . By $(\succ)$ DM's preference relation over P ($X \subseteq P$) is denoted. The relation $(p \succ q)$, $(p, q) \in P^2$ expresses the preferences of DM over P including those over X ($X \subseteq P$). The induced indifference relation $(\approx)$ is defined as (Fishburn, 1970):

$$((x \approx y) \Leftrightarrow \neg((x \succ y) \vee (x \prec y)), (x, y) \in X^2).$$

Let $(\int u(\cdot) dp)$ denote integration based on the probability measure p . A utility function $u(\cdot)$ is defined so that the following is fulfilled:

$$(p \succ q, (p, q) \in P^2) \Rightarrow (\int u(\cdot) dp \succ \int u(\cdot) dq).$$

In keeping with Von Neumann's axiomatic and utility theory, interpretation of the above formula provides that the integral of utility function $u(\cdot)$ is a measure for comparison of the probability distributions p and q defined over X . The assumption of the existence of a utility function $u(\cdot)$ leads to the “negatively transitive” $(\neg(p \succ t) \dot{\cup} \neg(t \succ q)) \dot{\supset} \neg(p \succ q)$ and “asymmetric” relation $(\succ)$ (Fishburn, 1970). These properties imply the existence of asymmetry $((x \succ y) \dot{\supset} \neg(y \succ x))$, transitivity $((x \succ y) \dot{\cup} (y \succ z) \dot{\supset} (x \succ z))$ and transitivity of the “indifference” relation $(\approx)$. In practice, the transitivity of the relations $(\succ)$ and $(\approx)$ is violated very often by uncertainty and DM's mistakes. The transitivity violation of the relation $(\succ)$ could be interpreted as a lack of information or a subjective mistake of DM. The transitivity violation of the relation $(\approx)$ is due to natural “uncertainty” of human's preferences and qualitative nature of expressions of the human's subjective notions and evaluations (Pavlov & Andreev, 2013).

There are several empirical methods for utility evaluation and necessarily all of them are based theoretically on the “lottery” (gambling) approach (Keeney & Raiffa, 1999; Fishburn, 1970; Farquhar, 1984). A “lottery” is every discrete finite probability distribution over X . The lottery is denoted as $\langle x, y, \alpha \rangle$, where α is the probability of the appearance of alternative x and $(1 - \alpha)$ – the probability of alternative y . The most widely used evaluation approach is the assessment (Keeney & Raiffa, 1999):

$$z \approx \langle x, y, \alpha \rangle, \text{ where } (x, y, z) \in X^3, (x \succ z \succ y) \text{ and } \alpha \in [0, 1]$$

The bottleneck of this approach is the transitivity violations of the relations and the so-called “certainty effect” and “probability distortion” (Kahneman & Tversky, 1979; Shmeidler, 1989). In complex situations, it is also difficult to determine the alternatives x (the best) and y (the worst) under the condition that $(x \succ z \succ y)$, where z is the analyzed alternative.

The measurement scale of the utility function $u(\cdot)$ originates from the mathematical formulation of the relations $(\succ)$ and $(\approx)$ and on the fact that the set of the probability distributions P , ($X \subseteq P$) is a convex set (Fishburn, 1970):

$$((q, p) \in P^2 \Rightarrow (\alpha q + (1 - \alpha)p) \in P, \text{ for } \forall \alpha \in [0, 1]).$$

These conditions determine the utility function $u(\cdot)$ over X up to an affine transformation, i.e. the interval scale. In the same scale is the measurement of temperature. Theoretically, the utility function $u(\cdot)$ could be build-up/ evaluated by pattern recognition of two sets that represent comparisons between lotteries (Aizerman et al, 1970; Pavlov, 2005):

$$A_u = \{(\alpha, x, y, z) / (\alpha u(x) + (1-\alpha)u(y)) > u(z)\},$$

$$B_u = \{(\alpha, x, y, z) / (\alpha u(x) + (1-\alpha)u(y)) < u(z)\}.$$

The notations x, y, z refer to elements of X and α is a uniformly distributed random value ($\alpha \in [0, 1]$) occurring in the lotteries $\langle x, y, \alpha \rangle$. The study uses a mathematical evaluation approach based on stochastic procedures perceived as machine learning based on DM's preferences. This mathematical approach is stochastic pattern recognition because ($A_u \cap B_u \neq \emptyset$). It means that the utility evaluation is a stochastic approximation with noise (uncertainty) elimination (Aizerman et al, 1970). The following represents the evaluation procedure (Pavlov & Andreev, 2013; Pavlov & Marinov, 2017). Let a sequence of learning points (x, y, z, α) (lottery $\langle x, y, \alpha \rangle$ and simple alternative z) be a set with probability distribution $F(x, y, z, \alpha)$ over $X^3 \times [0, 1]$. It is assumed that the "learning points" (x, y, z, α) are given by the probability distribution $F(x, y, z, \alpha)$ and in each point (x, y, z, α) DM compares the "lottery" $\langle x, y, \alpha \rangle$ with the simple alternative $z, z \in X$ ($\langle x, y, \alpha \rangle$ or $\approx$ or $\langle z \rangle$). Every DM's answer as preference refers to a discrete value, "better $\rightarrow, f(x, y, z, \alpha) = 1$ ", "worse $\leftarrow, f(x, y, z, \alpha) = (-1)$ " or "can't answer or equivalent $\approx, f(x, y, z, \alpha) = 0$ ". The discrete function $f(\cdot)$ denotes the qualitative DM's answer expressed as a preference which determines a learning point-training example $((x, y, z, \alpha), f(x, y, z, \alpha))$ and its affiliation to one of the two sets A_u and B_u . Every learning point refers to A_u ($f(x, y, z, \alpha) = 1$) with subjective probability $D_1(x, y, z, \alpha)$ and to B_u ($f(x, y, z, \alpha) = -1$) with subjective probability $D_2(x, y, z, \alpha)$. The vectors (x, y, z, α) could be got from pseudo-random sequences. By this way is formed a machine-learning training sequence of „learning points" (training examples). As the stochastic recurrent procedure for utility polynomial approximation is mathematical machine learning following the concepts of Aizerman et al, 1970; Pavlov & Andreev, 2013).

This collation is a subjective characteristic, representing the empirical knowledge of the DM or their intuition. The subjective and probability uncertainties and errors in DM's answers are taken into account as additive noise. This noise is denoted by the symbol ζ . The mathematical expectation of the noise ζ is proven zero (Pavlov, Andreev, 2013, 2017):

$$f(x, y, z, \alpha) = D_1(x, y, z, \alpha) + \zeta = 1 \text{ if } (x, y, z, \alpha) \text{ is referred to } A_u \text{ or}$$

$$f(x, y, z, \alpha) = D_2(x, y, z, \alpha) + \zeta = -1 \text{ if } (x, y, z, \alpha) \text{ is referred to } B_u.$$

The sets A_u and B_u overlap ($A_u \cap B_u \neq \emptyset$) because of the noise ζ . The probabilities $D_1(x, y, z, \alpha)$ and $D_2(x, y, z, \alpha)$ are exactly conditional mathematical expectations of $f(x, y, z, \alpha)$ over the sets A_u and B_u respectively (Aizerman et al, 1970; Pavlov, Andreev, 2013). In the chosen mathematical approach the probabilities $D_1(x, y, z, \alpha)$ and $D_2(x, y, z, \alpha)$ are stochastically approximated by a function of type:

$$G(x, y, z, \alpha) = (\alpha g(x) + (1-\alpha)g(y) - g(z)).$$

The function $g(x)$ is an approximation of the expert utility function $u(\cdot)$. Figure 1 shows three utility functions evaluated by the mentioned approach and developed mathematical procedures. The seesaw lines are approximations of the functions $g(\cdot)$ which appear in the formula of the function $G(x, y, z, \alpha)$.

A – passive teaching; B – active teaching through educational games; C – active teaching through virtual laboratories

Figure 1. Utility functions (the seesaw line is pattern recognition; the smooth line is utility polynomial approximation):

The function $G(x,y,z,\alpha)$ recognizes stochastically the two sets A_u and B_u (stochastic pattern recognition). The smooth lines are regressions of $g(\cdot)$ and de facto are approximations of the utility functions in the meaning of von Neumann (Pavlov & Andreev, 2013; Pavlov & Marinov, 2017). These functions are used in the process of modeling the *teachers' thinking*.

Value-Driven Decision Making and Control in Forest Ecological Management

In general, the economic evaluation of the forest is limited to the revenue from timber, although the forest offers many different benefits. Ecosystems as a whole could provide public services in different categories: material, energy, climate regulation, etc. The concept of multiple benefits of forests was developed rapidly in the 1980s and received a strong impetus from the United Nations Conference on Environment and Development in Rio de Janeiro in 1992. The economists, authors of the economics of ecosystem services study proved that maximum use of one forest service negatively affected the state of the others and ultimately led to the economic decline in the final product. The focus on forestry has shifted from timber production to a wide range of goods and services such as non-timber products, landscape design, and conservation of biodiversity (Erickson, 2002; Minnitt, 2007).

The concept of multiple forest benefits continues to evolve today. When taking into account the abovementioned, the following case is studied. Suppose a businessman apply to lumber in a particular forest and propose a business plan to the economics ministry. The administration uses an information system for decision support in which the value (utility) based model is constructed by specialists, scientists, ecologists, and economists. The system determines the optimal parameters of the business plan using the quantitative value-based model and the built-in utility function. The government employees make a decision based on the proposed optimal modeling scheme. According to the case study, the main objective of the investigation is:

To develop a value-based model (VBM) for integrated assessment of economic, environmental and social services of forest ecosystems, which could be applied for monitoring and forest ecological management or control of forest areas and allowing the sustainable development of business and natural resources used.

A value-based model was developed and focused on the preferences of an expert in ecological and economic management. This model was integrated into the ForEco system (Lyubenova et al, 2015). It was recognized that expert preferences could play a crucial role in the decision-making process. For the

modeling purposes, the authors accept three forest ecosystem indicators (sub-objectives or factors) that adequately describe the main objective of investigation following the DM's opinion:

- X_1 – timber reserves ($\text{m}^3.\text{ha}^{-1}$) as the representing criterion for the assessment of economic impact or material services;
- X_2 – species richness ($\text{n}.\text{ha}^{-1}$) as the representing criterion for the assessment of environmental impact, or regulatory and support services;
- X_3 – the percentage of the population employed in the forestry sector as the representing criterion for the assessment of social effect or services.

The value model is developed as a multi-attribute utility function with the three factors mentioned above. The carried out expert analysis and organizational structuring led to accepting the following sub-objectives and the appropriate sub-criteria, which adequately describe the main objective and are real, physically measured quantities. The domain of variation of representing criteria is determined in Table 1.

Table 1. Forest ecosystem indicators (factors) and their assignment to the attributes of the utility function

Factor	Denotation	Significance	Measuring units
X_1	material services as a volume of timber per hectare	economic impact	10 to 300 [$\text{m}^3.\text{ha}^{-1}$]
X_2	regulatory and support services	ecological impact	1 to 200 [number of species per hectare]
X_3	the percentage of employed locals in the forestry sector	social effect	1 to 30[%]

In the process of investigation, the DM found independence by utility between the following factors:

- X_2 from X_1 and X_2 from X_3 ;
- X_3 from X_1 and X_3 from X_2 .

The first utility independence means that the preferences of DM between lotteries for x_2 at different values of x_1 and x_3 do not change (Keeney & Raiffa, 1999). That suggests utility independence of x_2 from the changes of the other two factors. Whatever the wood reserves in the forest ecosystem are, the employment of the population in the forestry sector may be different, but in any case, the preferences are directed to the preservation of vast richness of species in the forest.

The preferences of DM between lotteries for x_3 at different values of x_1 and x_2 do not change, suggesting utility independence of x_3 from changes of the other two factors. Thus, despite the reserves of wood and diverse species in the forest ecosystem, the preferences are aimed at increasing the number of workers in the forestry sector. Low timber reserves and scant species composition are motivation for an increase of employment in the forestry sector because of the need of reforestation, regeneration, cultivation of existing forests, optimization of forest-related natural resources, development of alternative use. High timber reserves and richness of species composition are motivation for an increase of employment due to opportunities of multifaceted use of forests and the need for environmental management and balanced utilization of forest resources.

Using the theory for the decomposition of multi-attribute utility to simpler functions given in (Keeney & Raiffa, 1999) the following multi-attribute utility structure is determined:

$$\begin{aligned}
 u(X) &= k_1 u(X_1; X_2^o; X_3^o) + \\
 &+ f_2(X_1) \times [u(X_1^o; X_2; X_3^o)] + \\
 &+ f_3(X_1) \times [u(X_1^o; X_2^o; X_3)] + \\
 &+ f_{23}(X_1) \times [u(X_1^o; X_2; X_3^o)] \times [u(X_1^o; X_2^o; X_3)], \\
 \text{where } &u(X_1^o; X_2^o; X_3^o) = 0 \text{ and } u(X_1^*; X_2^*; X_3^*) = 1.
 \end{aligned}$$

In the formula above $X^o = (X_1^o; X_2^o; X_3^o) = (10, 1, 1)$ and $X^* = (X_1^*; X_2^*; X_3^*) = (300, 200, 30)$. The functions f_2 , f_3 , and f_{23} have the forms:

$$\begin{aligned}
 f_2(X_1) &= u(X_1; X_2^*; X_3^o) - k_1 u(X_1; X_2^o; X_3^o), \\
 f_3(X_1) &= u(X_1; X_2^o; X_3^*) - k_1 u(X_1; X_2^o; X_3^o), \\
 f_{23}(X_1) &= u(X_1; X_2^*; X_3^*) - f_2(X_1) - u(X_1; X_2^o; X_3^*).
 \end{aligned}$$

Each of these functions was evaluated based on the DM's preferences. The described value modeling is a part of the Smart Forest Ecological Management System ForEco, which is based on Open Data and FIWARE (Lyubenova et al, 2015).

Potential users are forest and landscape policymakers in governmental and municipal institutions managing the following activities:

- Planning new forests in an environmentally friendly way with minimal negative influences;
- Guiding forest managers and planners to choose, if possible, suitable native species, to ensure the sustainability of the environment;
- Managing cost-effectively forest resources;
- Evaluating alternative strategies, provision of comparable forecasts, etc.

Other prospective end-users are companies and experts from the Green Economy, Agricultural and Forestry sector, as well as – research and innovation organizations.

The aim is to build a utility (value) based model that can be used for value-based modeling and management, even for value-based optimal control, taking into account the environmental, social, financial impact on the local population. For this purpose, a model developed by Hotelling is used (Hotelling, 1931; Clarke, 1983; Cairns, 2018; Di Vita, 2011). A logging model of forest areas of the following type is chosen.

$$\begin{aligned}
 \dot{y} &= -\min(z, v)r(y), \\
 \dot{z} &= \gamma w, \\
 y(0) &> 0, z(0) > 0, \\
 0 &\leq v, 0 \leq w, (v + w) \leq L(t).
 \end{aligned}$$

In the above formula, $y(t)$ refers to “extracted woods per hectare” [$\text{m}^3.\text{ha}^{-1}$]. This new meaning of X_1 is just a demonstration of the model. The variable (z) indicates the capital invested in the equipment and (v) is the labor as a workforce (one man – one shovel). Both dimensions are in standard units (for example, money in BGN, utils). The variable (w) indicates the portion of labor used in the production of the equipment. As an optimal control criterion, an integral is selected:

$$\int_0^T \exp(-\delta t)(\pi \min(z, v)r(y) - \alpha v - \beta w)dt.$$

This integral has the meaning of net income. With (T) is indicated a period of work, (π) is the price of the timber, (δ) is the devaluation factor over time, (α) and (β) are respectively the value of labor force and capital investments. Regardless of relatively simple description, determination of the optimal solution requires a special technique, namely non-smooth analysis and optimization (Clarke, 1983). The solution includes the following three steps (time intervals):

- first step – the solution is $(v, w) = (z, L(t) - z)$
- second step – the solution is $(v, w) = (z, 0)$
- third step – the solution is $(0, 0)$

The first and third steps may be missing depending on the parameters and initial conditions. The modeling is performed with the parameters presented in Table 2: The function $r(t)$ is the utility function, or could be the derivative of the utility function in others models, depending on the semantic. The logging is carried out under conditions of 5% social effect (X_3) and the number of tree species/ species richness in the forest ($X_2=20$).

Table 2. Parameters of the model

Value	Quantity	Measuring; Meaning
$y(0)$	150	$\text{m}^3.\text{ha}^{-1}$
T	10	month
L	80000	BGN
α	30	BGN
β	20	BGN
δ	0.3	devaluation factor
$z(0)$	25000	BGN
γ	1.7	coefficient of technology efficiency
$r(t)$	-	utility function
X_3	5	%; social effect
X_2	20	number species per hectare

Figure 2 shows the optimal variations over time of the yield in cubic meters per hectare and the capital invested in equipment, as well as the change over time of the parameter w (labor employed in the production of the equipment).

Figure 2. Utility forest ecological modeling and control: A – optimal control solutions; B – Utility function

The calculation is demonstrative. It illustrates a mathematical description of the problem and takes into account complex social and economic effects with precision in logging management according to DM preferences. The function $r(t)$ could also be a derivative of a utility function, depending on the way that such a utility function is evaluated.

Value Modeling of Active and Passive Technology-Based Resources in Classroom Teaching

Control and management of an education process in schools is a complicated and tough task, even with the help of contemporary technology. There are developed different kinds of decision-support information systems that provide educators and teachers with tools that enable planning, implementing, and controlling the typical activities in teaching practice in terms of providing resources, creating curriculum, lesson planning, and related issues (Passey, Breiter, & Visscher, 2013). Kalay & Chen (2002) examined the effect on students of integrating a decision support system into a school and find a significant improvement in students' achievement. Here is presented a value-based model that concerns the optimal usage of active and passive technology-based resources in classroom teaching. The proper allocation of diverse types of learning resources and the use of various pedagogical methods are vital for the effective teaching process. The methodology enables mathematical modeling and management, even control and prescriptive decision support in such complex processes. The authors apply the evaluation of utility functions for representing the subjective preferences of teachers who have a long-standing practice of using ICT resources in classroom activities. For the current study, three technology-based teaching approaches are chosen because of their frequency of usage and usefulness. In the context of school education presentations, virtual laboratories and educational games are the most appreciated (Terzieva, Todorova, Kademova-Katzarova & Andreev, 2016). These tools sufficiently fulfill the requirements of the essential pedagogical methods – information, phenomenological and cooperative and enable combining passive and active teaching approaches:

- Passive – through a presentation (acquisition of information from e-textbooks, videos, animations);
- Active – through a virtual laboratory (experiment, phenomena observing, results' discussion);
- Active – through learning games (application of acquired knowledge and skills, acquisition of new knowledge through communication, cooperation and negotiation with other participants).

The research founds on the results of an online questionnaire that covers broad topics related to the implementation of ICT in teaching practice. Thus, it is enabled an extensive investigation of factors such as types of used teaching activities and technology-based resources, as well as their frequency of usage (Terzieva et al., 2016). The survey findings representing the opinion of 190 teachers from different regions in Bulgaria serves as input data for current research. Prevail respondents with more than 15 years of professional experience (54%) from primary and secondary schools. As a method for carrying out the survey, a questionnaire distributed through e-mail invitations was selected. They were targeted at teachers attending forums for innovative teaching methods based on ICT, so most answers are from teachers with good technology experience. Although in a sense it is a constraint, this fact contributes to comparatively accurate results, as the global trend in education is the widespread integration of technology. Therefore, the suggestions derived from technology well-skilled teachers for an optimal usage ratio of active and passive technology-based resources in classrooms are indicative of modern teaching process.

Initially, to design a quantitative utility model that describes the tackled problem, its structure consisting of the main objective, sub-objectives and relations between them have to be defined. For the current task, the main objective is to assess and analytically represent the usefulness of ICT-based teaching approaches. The sub-objectives are to detect the subjective preferences of teachers for the correlation of *passive* and *active teaching* approaches and ratio within active teaching (*educational games/virtual laboratories*). Further, in formulae, these approaches are considered as variables denoted as y , x_G and x_L respectively.

Having in mind the described model the multi-attribute utility function is determined as a function of three variables that represent the mentioned teaching approaches. This function is constructed in the frames of the von Neumann axiomatic approach of decision-making theory in conditions of uncertainty with the use of recurrent stochastic procedures for utility approximation (Keeney & Raiffa, 1999).

SOLUTIONS AND RECOMMENDATIONS

Optimal Usage of Active and Passive Technology-Based Teaching

The following section describes the implementation of organizational knowledge in the process of modeling of the educational system at a school level. In particular, it concerns the determining of the proper use of active and passive technology-based teaching approaches through evaluation and analysis of the subjective preferences of teachers.

The authors propose a solution to the issue through the multi-attribute utility function evaluated by decomposition into single variable functions, following the structure of the problem. The separate examination of the usefulness of each teaching method, need the teachers' preferences to be explicitly presented as three single-attribute utility functions $f(\cdot)$, respectively for *presentations* $f_3(y)$, *educational games* $f_1(x_G)$ and *virtual laboratories* $f_2(x_L)$. They are constructed by an implementation of the above-described mathematical approach. These functions represent the usage of passive and active ICT resources in knowledge delivery and classroom training. The measuring unit for the three variables of the

functions is hours. The decomposition is based on the expressed utility independence in the frame of the multi-attribute utility theory. The considered sets $X_G=[0-40]$ h, $X_L=[0-40]$ h, and $Y=[0-40]$ h represent scales related to the above sub-objectives. The authors assume that the school week has a total of 40 hours and the teaching is conducted only through the researched approaches. The mentioned above “lotteries” are discrete finite probability distributions over Cartesian product $X_G \times X_L \times Y$. It is assumed that $z_1 = (x_{G1}, x_{L1}, y_1)$, $z_2 = (x_{G2}, x_{L2}, y_2)$ and $z = (x_G, x_L, y)$. Then a lottery used in the process of evaluation is denoted as $\langle z_1, z_2, \alpha \rangle$, where α is the probability of appearance of the alternative z_1 and $(1 - \alpha)$ is the probability of the alternative z_2 . The approach used for evaluation is described in (Keeney & Raiffa, 1999; Pavlov, 2005):

$$z \approx \langle z_G, z_L, \alpha \rangle, \quad z_G, z_L, z \in X_G \times X_L \times Y, \alpha \in [0, 1].$$

A profound investigation of the problem under consideration implies utility independence among the following factors, determined by decision-makers:

- $X = X_G \times X_L$ from Y and vice versa,
- X_G from X_L and vice versa.

The DM assumes the factors X and Y as mutually utility independent, so the multi-attribute utility function is theoretically presented as follows (Keeney & Raiffa, 1999).

$$U_{12}(x_G, x_L) = k_1 f_1(x_G) + k_2 f_2(x_L) + k_{12} f_1(x_G) f_2(x_L),$$

$$U_{123}(x_G, x_L, y) = b_1 f_3(y) + b_2 U_{12}(x_G, x_L) + b_{12} U_{12}(x_G, x_L) f_3(y)$$

Here $k_1, k_2, k_{12}, b_1, b_2$, and b_{12} are constants whereas $f_1(\cdot), f_2(\cdot), f_3(\cdot)$ are above-mentioned single-attribute functions. These constants and utility functions are evaluated by stochastic approximation procedures of the potential function method in the frames of the discussed above evaluation approach (Keeney & Raiffa, 1999; Pavlov, 2005). For example, the evaluation of $f_1(x_G)$ consists of the following steps:

- DM compares the “lottery” $\langle x, y, \alpha \rangle$ with the simple alternative z , where the variables $x, y, z \in X_G$, $\alpha \in [0, 1]$, x_L and y are fixed at chosen values;
- A „learning point” (training example) $((x, y, z, \alpha), f(x, y, z, \alpha))$ is determined;
- A training sequence of a finite number of “learning points” (training examples) is used in recurrent stochastic procedures for utility polynomial approximation;
- The same steps are used for preference-based utility evaluation of the functions $f_2(\cdot), f_3(\cdot)$ and the appropriate coefficients and by fixing the rest part of variables at chosen values.

Figure 1 shows the constructed single-attribute utility functions that imply the following considerations. Figure 1A presents the utility function of the passive teaching method. When insufficient, it is practically zero. At least 10 hours a week of passive teaching are required to achieve a utility of about 50%. The optimal number of hours spent on this teaching approach is within 15 to 24 (a utility of over 80%). When passive teaching exceeds 30 hours, the utility function drops, but even in using this approach all the time, the utility does not fall below 30%.

Figure 1B shows the utility function of the active learning method through learning games. The optimal use of this approach is between 8 and 16 hours: the utility in this range is over 80%. The utility curve increases steeply at the beginning, which means that even with relatively little use of learning games, a positive effect in learning can be achieved. Usage of a game-based approach over 20 hours per week is not beneficial and not advised.

The utility curve of using a virtual laboratory has a very different shape (Figure 1C). Remarkably, even with very little use of such an instrument, the utility is very high – from 50% upwards. The maximum is between 6 and 20 hours (over 80%), then the utility decreases and the usage of over 30 hours is not efficient for the learning process.

For the three teaching methods, the curves have rounded maxima. It means that there are wide intervals where changes in the use of these methods do not significantly affect their effectiveness. Thus, the teacher can use various combinations of different learning methods and tools within the framework of a specific situation.

The utility functions and the evaluated coefficients obtained for each of the teaching methods examined, allow constructing surfaces that represent their mutual effect in a general multi-attribute utility function. As the authors assume a school week of 40 hours, the variables associated with the applied teaching approach are related by the formula:

$$z_G + z_L + z = 40, \quad z_G, z_L, z \in X_G \times X_L \times Y.$$

Figure 3 shows this correlation between the parameters as a graphical surface of the aggregated multi-attribute utility. Figure 3A presents the utility function of the two active methods considered – educational games and virtual laboratory when the variable of passive teaching is determined as $z = 40 - z_G - z_L$. Figure 3B depicts the utility function for the mutual effect of the active teaching method through educational games and the passive one as $z_L = 40 - z_G - z$. Similar is the surface of the multi-attribute utility function for the mutual effect of the active teaching method through virtual laboratory and the passive one, so it is not presented.

Figure 3. Multi-attribute utility functions representing the mutual effect of: A – active teaching through educational games and virtual laboratory ($z = 40 - z_G - z_L$); B – active teaching through learning games and passive approach ($z_L = 40 - z_G - z$)

Since the accurate reading on the vertical axis is hard in three-dimensional graphics, the projection of the utility function's isohypses (height contours) is used. The perspectives of these graphics are chosen in such a way that these projections are well visible and readable. The desired percentage of the utility function can be selected. Thus the boundaries of an area where can be found possible suboptimal solutions for an effective teaching-learning process by combining different teaching approaches are determined. Teachers can decide in each particular circumstance according to many factors (e.g., school stage, learning subjects, administrative requirements, and students' knowledge) what percentage of the utility function to choose for achieving educational goals. For example, Figure 3 illustrates 75%, 80% and 85% utility that forms a satisfactory area for application of considered pedagogical approaches.

These graphics indicate clearly that even minimal use of a virtual laboratory in teaching has a positive effect, while excessive usage is not relevant. In educational games, both extremes are not recommendable. The passive learning method requires at least about 10 hours a week to have some effect, and its excessive use is not optimal but still reasonable.

The users that can benefit from considered preference-based utility approach are school, administrative and other education-related policymakers that are responsible for ensuring an efficient and contemporary teaching process. The aim is to build a utility (value) based model of teaching that can be used for management and value-based optimal control, taking into account the innovative teaching approaches and their educational and psychological impact on students. In a school context, this model can be a part of an information system that supports the management of the following tasks:

- Evaluating the usefulness of teaching approaches and various teaching resources;
- Guiding and supporting the teachers to choose and blend different teaching approaches and resources for their implementation;
- Supporting decision making based on teachers' preferences to ensure the effectiveness of the teaching process;
- Planning the lessons in a sub-optimal, learner-focused manner with minimal negative influences;
- Managing the efficient achievement of educational objects.

FUTURE RESEARCH DIRECTIONS

There is no doubt that ICT will become increasingly important in education as in all areas of society. It is also indisputable that everything has both a positive and negative impact. Hence, in the decision-making process it is essential to take into account the opinion, experience, and recommendations of experts and those who use in practice new technology resources considering as follows:

- what is particularly useful and should be further developed
- what should be improved
- what is a flaw
- what is inappropriate and has to be discarded

To this end, surveys are being conducted, raising arguments in support of research into the following issues: the usability of ICT products, their degree of usefulness and their application in different contexts of the teaching-learning process. A further concept is to develop an appropriate methodology for using the data from surveys, thus to perform research on the usefulness and benefits of each technology tool

or resource based on the aggregated opinion of many experts, not just of individual expert's knowledge and intuition. The described value-based approach is particularly appropriate for profound investigations of mentioned issues.

The presented methodology and value-driven modeling create an environment that enables optimization by offering a general objective function. The model takes as input the essential attributes of the designed system and gives as outputs a score. Such value or utility functions reflect human knowledge and intuition expressed as preferences within the framework of the system and objective. The human's thinking, notions and preferences have cardinal significance, but the value-based decision and control require quantitative information. The machine learning in mathematical meaning also needs analytical presentations. These are two contradiction issues with their particular requirements. This preference informational level imposes the need for new approaches and algorithms for the inclusion of value-driven management and control in the decision-making process in a harmonious way. The well-grounded and precise mathematical approach to this problem requires the usage of achievements of the measurement theory (scaling), utility theory, decision-making theory (normative and prescriptive approaches), probability and statistics and some results from optimal control theory (Pavlov & Marinov, 2017).

CONCLUSION

A possible solution for value-utility preference-based evaluation and representation is the stochastic approximation used in an environment of a gambling approach to express the human's knowledge as preferences. In that manner, the incomplete information for mathematical modeling and decision making in complex systems is compensated with the measurement of qualitative human preferences. The discussed two models are examples of such modeling of complex processes.

The first value-based model for integrated assessment of economic, ecological and social services of forest ecosystems is a mathematical model of the kind "human-dynamical production" taking into account the complex social and economic characteristics of the timber production process. This model allows optimal control determined in line with the DM's preferences regarding the three factors, logging, social effect and salary and ecology on the forest.

The second value-based model concerns the profound exploration of the use of technology-supported resources that enable efficient teaching process. The implemented mathematical procedure determines the utility functions of considered passive and active teaching approaches. It takes into account the usefulness of employed resources and their frequency of usage in teaching context by recognizing teachers' opinions expressed in an online survey. In practice, the obtained utility functions serve for reasoned suggestions about efficient integration of technology-enhanced teaching approaches. Additionally, these functions allow educators to construct multiple instances of different optimal combinations of technology-supported active and passive resources according to their preferences and specific learning objectives. The applied mathematical approach is flexible and can meet the requirements and particularity of each school subject.

The purpose of this chapter is to demonstrate that the proposed specific mathematical utility approach makes systems engineering value-based strategy practically feasible under different specifications. It is also applicable in different countries depending on the particular parameters of particular tasks and decision maker's preferences represented by the polynomial of the utility function.

KEY TERMS AND DEFINITIONS

Active Teaching Resource: A resource used in active teaching approach – both the teacher and learner actively participates in the process of knowledge acquiring (e.g., discussion, laboratory experiment, simulation, group project, educational game).

Complexity: A condition of a system or situation integrated with some degree of order but with too many elements and relationships to be understood in a simple analytic or logical way. In the extreme, the complex system or situation is with multiple and diverse connections with dynamic and interdependent relationships, events, and processes.

Machine Learning: A computational methodology for automatic information collection and knowledge descriptions aimed at improving solutions of tasks from real practice and experience.

Model-Driven Decision-Making and Control: An emphasized access to and manipulation of a statistical, financial, optimization, or simulation model. It uses data and parameters provided by users to assist decision process in analyzing a situation.

Passive Teaching Resource: A resource used in passive teaching approach – teacher presents learning matter, the learner only passively receives knowledge (e.g., narrative, presentation, lecture, demonstration, text).

Util: A microeconomics' standard unit of measurement of the utility.

Utility Independence: An attribute A1 is utility-independent of attribute A2, if conditional preferences on lotteries on A1, given at a fixed value of A2, do not depend on that fixed point. The utility independence is not symmetrical.

Utility Theory: A normative approach to the issue of how people should rationally choose in conditions of uncertainty.

Value-Driven Design: A system engineering strategy, which enables multidisciplinary design optimization. It creates an environment for optimization by providing designers with a value function as objective or as part of the mathematical model.

A Nemetic Model for Transmedia Organizational Literacy

2

INTRODUCTION

The exponential proliferation of information in digital society, and the increasing complexity of processes and interactions in a hybrid world where humans and machines collaborate on an equal footing has resulted in an explosion in the number of “wicked problems (Churchman, 1967)” humanity is faced with.

The increasing diversification of interconnected media platforms, which provide a complementary complex discourse, demands an effective use of the space that is now called “transmedia.” This article provides terms and definitions for transmedia and for the new set of personal skills and abilities required to participate in it, “transliteracy.” It also presents the nemetic system, which facilitates analyzing, tracking and visualizing communication interactions in virtual transmedia environments.

Since humans started to use both gestural and oral codes to communicate, messages have been elaborated and expressed differently when different communication channels were in use. In recent times, with the dawn of radio and television, that fragmentation of content has become of interest to researchers (Steinberg, 2012) and has been identified as a characteristic of mass media (McLuhan, 1994).

With social media, content is fragmented across multiple virtual and physical platforms, with varying degrees of interaction that add complexity to social communication. Interactivity among multiple authors and multiple audiences generates dynamic “cross-media” seriality or “transmedia narrative” that has been studied from educational, entertainment and sociological points of view (Dena, 2009).

Learning to use these media requires skills beyond the traditional listening and reading, to be able to integrate multiple messages in multiple codes, as an essential skill both for personal and professional communication. This transliteracy is a complex ability of intertextual navigation, the strategy for coding and decoding the multi-discourse in the digital ecosystem.

These recursive communication experiences are the subject of recent research that explores cognitive patterns in narrative that can be represented through geometric models, consolidating the use of the term “fractal narrative” in the transmedia context (Duarte, 2014). The aim of this multilevel analysis is to take into account individual discourse (micro level), collective interaction (meso level) and community knowledge building (macro level).

Because so much of personal and professional life is becoming ever more dematerialized, it should not be surprising to learn that organizations can now be defined and understood through the way that

DOI: 10.4018/978-1-7998-3473-1.ch022

these flows are expressed and regulated. Nematics offers a simplified sequence and code to express and visualize these interactive communication processes in the transmedia ecosystem to facilitate organizational development (De, 2014).

BASIC CONCEPTS

Transmedia

In an era where artificial intelligence (AI) is driving interactions between humans and machines, the concept of transmedia has evolved from its origins as an extension of media story telling across platforms into a dynamic ecosystem for organizational transformation.

The term “transmedia” is attributed to Marsha Kinder, who in 1991 used it to refer to an emerging entertainment supersystem, involving intertextuality and multiple sources with different levels of interaction (Kinder, 1991). It applied to tools, processes and concepts, and opened the door to media that had not been invented then, such as wearables, implants, or augmented reality devices.

In 2003 Henry Jenkins described a process of “transmedia storytelling” in which “each medium does what it does best, so that a story might be introduced in a film, expanded through television, novels, and comics, and its world might be explored and experienced through game play” (Jenkins, 2003). Later, he defined transmedia storytelling as a process “where integral elements of a fiction get dispersed systematically across multiple delivery channels for the purpose of creating a unified and coordinated entertainment experience” (Jenkins, 2007).

This notion of multiplatform narrative has expanded to encompass every type of human communication, including marketing (Tenderich, 2014), political debates (Costanza-Chock, 2014), or personal learning networks (Richardson & Mancabelli, 2011). Transmedia expands human relationships in virtual spaces, and is starting to enhance communications capabilities through hybrid human-machine interactions.

Hybrid Communication

At the time of this writing, AI technologies such as machine learning, natural language processing, image recognition, and their various applications are pulling transmedia practice into the world, not only of human-machine interaction, but of active human-machine collaboration. Until recently, human-machine interaction has primarily referred to software interfaces. The evolving digital landscape is now producing situations where non-human agents take a role as collaborators in a group or community, creating hybrid communication and collaboration between human and non-human agents (Lorenzo Galés & Gallon, 2018). Transmedia systems are mediated by “intelligent” non-human agents (e.g. personal assistants such as Amazon Echo, Apple Siri, or Google Home); customer experiences are being managed by AI-driven chatbots; human resource managers, medical practitioners, and law enforcement agencies are all interacting with, and depending on, various types of “intelligent” transmedia devices not only for information, but for decision-making.

But these types of interaction are just the beginning. Emerging technologies are adding to the complexity of our informational environment. They are allowing humans to expand their sensorial perception, and forcing organizations to rethink their structures and processes.

A technology like blockchain, which is invisible to the user, none-the-less engenders an upstream reflection about who is trustworthy, and the nature of trust in the context of a given information set that

is revolutionizing the world of e-commerce, electronic contracts, diplomacy, and all types of sensitive transactions.

The artist Aiste Noreikaite has built a helmet that converts brain wave signals into musical sounds that correspond to the user's different brain states (Chung, 2015). This is a new type of interface that provides humans with extra-sensorial information that breaks down the traditional idea of five senses (sight, sound, smell, taste, touch) and recognizes a continuum that still needs to be identified, categorized, and interpreted by human culture. This enhanced, hybrid interaction promises new typologies of messages which, combined with AI, can create new opportunities for feeling, thinking, and doing – individually and collectively.

Transliteracy

The evolution from media to transmedia requires individuals to pass from personal, linear communication skills and abilities (reading, writing, speaking, etc.) to intertextual skills. They include not only analogy, correlation, mental association, context awareness, or synthesis, but also empathy, engagement, and other emotional appreciations, essential to integrate and combine fragments of meaning into the holistic comprehension of a story, concept, or collaborative activity.

The combination of these complex abilities can be understood as a new competency called transliteracy. Transliteracy has been defined as “the ability to read, write and interact across a range of platforms, tools and media from signing and orality through handwriting, print, TV, radio and film, to digital social networks” (Thomas, 2005, Thomas et al. 2007).

In transliteracy, a coherent discourse is perceived through a series of transmedia fragments. It requires participants to move from discrete, perceptive skills to compound, intangible projective skills that can facilitate strategic thinking and collective problem solving. Interactions such as debating, negotiating, conciliating, or collaborating on social platforms are high value-added skills and become the energy for emerging collective creativity.

In an era of growing complexity, the capacity to construct holistically across a series of fragments is becoming an essential competence for leadership in organizations. Transmedia literacy skills are acquired by communication and interaction across different informational ecosystems. Their development requires participation and engagement in different social media, connected to relational capabilities and social abilities. The ultimate aim of this interaction is to collaborate actively in conversations, events, and shared projects in virtual spaces. While transliteracy can be seen as a human adaptation to new communicative environments, it also implies self-management, interpersonal behavior, and social self-regulatory abilities.

In organizations and institutions, emotional intelligence in leadership has become an essential executive strategy for building trust and increasing the ability to convince and engage others in direct action.

The Nematic path (Notice, Engage, Mull, Exchange) recalls the traditional empirical research method, starting with individual observation and progressing toward collective conceptualization, but it also leads directly to action, through sharing ideas, building common meanings, creating mutual understanding, and envisioning collaborative projects.

This proactive nematic design correlates with several emerging design-thinking processes for organizational action, such as Design for Change, an international program based on four steps (Feel, Imagine, Do, Share) to promote and evaluate social participation among students and young citizens (Bapna et al. 2015). Executive leaders can form and join transmedia networks where they work together to design and execute real-world projects through international collaboration.

Both transmedia and transliteracy are changing the way we perceive learning and professional training at all levels, and how we organize professional environments. Hybrid communication skills are now necessary to understand and produce useful knowledge (Lorenzo Galés & Gallon, 2018) and are more and more related to the abilities to create, join and maintain communities of interest, and build personal digital networks (Rajagopal, 2012).

From an individual point of view, users learn multiple literacies by actively harnessing different competences in relationship with each other. From a collective point of view, organizations identify and empower the use of those transliteracies that help the organization to build internal cohesion and integration, and to develop more proaction and openness to the rest of the community and the world. This tends to coincide with the global competencies cited by the Organization for Economic Cooperation and Development (OECD) as essential for the 21st century (OECD, 2017).

Nemetics

Where transmedia is the framework for communication, and transliteracy is the skill for interaction, Nemetics is the analytic tool. Nemetics functions as a fractal meta-language that facilitates communication among researchers in different disciplines to debate about complexity. It is based on strategical models, and is independent of specific content.

The essentials of Nemetics can be summarized in a simple mnemonic acrostic, which describes learning in any context at any level. At its most effective it is:

- Notice without preconceptions (N).
- Engage without judgment (E).
- Mull before communicating or acting (M).
- Exchange in the appropriate way and time (E)

This basic path (Notice. Engage. Mull. Exchange), recalling the traditional Bloom taxonomy (Anderson et al. 2001), retrieves four action levels that may or may not be performed during interactions (after each verb, add the option, “or not”). With this simple structure, nemetics provides identified sequences, quantifiable interactions, and visualization of results that can be expressed with simple drawings and objects. The whole process is then conceptualized as a single identified process, a NEME that can be seen as a coherent unit, represented visually by the interactions that took place during the debate, as in Figure 1A.

Figure 1. Simple visualization of the fractal nature of nematic sequences

Source: Michael Josefowicz

These basic communicational units are self-similar and can be fractally combined and recombined in a variety of ways to visualize complex exchanges. Figure 1B shows four discrete nemes, but these exchanges can also be connected with larger discussions, and so can be integrated into more complex sets of multi-party exchanges (Figure 1C). The two larger nemes thus produced can also be integrated into a more complex network exchanges (Figure 1D) and this can continue to as high a level of complexity as necessary to define a complex series of patterns and waves of exchange. This model offers extremely rich information (big data) both about the media environment and the participants.

A neme can thus be defined as a bounded network of networks that, at the same time, is the channel and the product of energy transmission. In a nemetic sociogram, conversations would be seen as a result of peoples' interactions, and as a node integrated into a larger network in an expanding conceptual territory. It is both a conversation and a (holistic) topic.

At the individual level, a neme translates as a meta-cognitive routine, the smallest representation of a signal passing from any node to any node in any network in one step. At collective levels, the study of neme patterns can be useful for showing mental models that can serve as universals in further communicative analysis, and in designing debate strategies.

Taken as a unit, a neme routine - that concludes with consensual knowledge - can be the starting point from which new debates can arise. This recursivity had already been studied in The Knowledge Forum, another international Computer Mediated Communication experience (Bereiter & Scardamalia, 2006), and has long been identified as a path into high order thinking (HOT) processes (Rehage, 1994). It is now also applicable to the study of machine learning algorithms, and the AI ecosystem created by their accumulation and interactions. This field is to be developed not only by computer scientists, but by users who are aware of their interactive processes, their learning needs, and their organizational potential.

From routine building to big data analysis, nemetics includes the dimension of self-reflection, professional development, and organizational transformation. The obtained global vision contributes to leadership and resource management, focused on integrated learning - self and collective - and helps expand consciousness and engagement towards complex problem solving.

Nemetics helps express a new way of thinking about human communication that involves co-creation in complex adaptive/creative environments. Nemetic research itself evolves by reproducing experiences of transliteracy in a large variety of transmedia and multi-contextual spaces:

Care is taken not to define the discipline or its boundaries very rigidly. This is because once it is rigidly defined it also rigidly limits the development of the subject, its evolution and expanse it might cover. In short, any rigid definition would limit the discipline's adaptability to future changes in human conceptual understanding and knowledge or application in a different domain than what is envisaged right now" (De, 2012).

Used as the meta-language for recursive analysis, nemetics shows interactive thinking processes, collaborative debates and a collective cognitive resonance, through debate, discussion, negotiation, and compromise. It has allowed networks to research and exchange about innovation, education, history, political economy, design, or art across the fields of different disciplines, specialties and cultures.

This nemetical world is hierarchical, in the sense commonly used in complexity discourse, and it is composed of several nested spheres that represent different levels of interaction. Each sphere nested within a larger sphere is a larger or smaller nemetic structure. It is fractal in the sense that such networks are scaled and context independent. At every level they are self-similar to the levels closer to the center of the sphere and further away from the center of the sphere. Any sphere can be seen as a NEME, where

Figure 2. Spheres of nested complexity

Source: Daniel Durant, used by permission

the proximate inner sphere is the source of energy. The proximate outer sphere is the source of constraints [Figure 2]. In addition, there are flows of energy within and between spheres.

This nematic code can be used as a common language to shape complexity, and the fuzziness of the code is the source of its strength. Applied to organizations, nemes become unit plans for specific projects, and also a macro view of how the projects interact to create the global organizational program. It is also possible to extend this to a wider macro view, at regional or national level, to take into account, for example, institutional initiatives to slow down climate change, and marketing procedures in private enterprises. By quantifying these two initiatives in the same territory, we add relevant social information to the pool of big data. Analysis of their parallel evolution would allow community leaders to discover common goals and possible partnerships.

NEMETICS RESEARCH: USING TRANSMEDIA IN ORGANIZATIONAL DEVELOPMENT

Theoretical Context

The multilayer nemetics system provides a methodology for connectivist action-research and action-reflection in transmedia, including several meta-codes for visualizing procedures and results. In transmedia, users are producers, and the process is the product. It can be seen as flows of data and information through multiple channels. Nemetics provides a sequenced approach for organizations to articulate the structure and mechanisms of those flows:

- Identifying, explaining, and interpreting interactions in various media, to analyze their evolution (notice).
- Promoting organizational learning by exploring new communication spaces, to improve teamwork and community building (engage).
- Reflecting on the different transliteracies needed to apply the nemetic model effectively in different situations, and the results that follow from implementations (mull).
- Creating local and global actions to benefit from the strategies developed, and follow through with other people and organizations implicated in the process (exchange).

In addition to being an acronym for Notice, Engage, Mull, and Exchange a neme is defined as a basic communicative unit, analogous to a neuron in biology. Data is transformed to information in one neme. The information is passed along to another neme which creates richer information. Bundles of interlocked nemes, like bundles of neurons, form networks of nemes, and then networks of networks.

The name “neme” was chosen to sound like gene and meme. The gene is the basic unit of biological reproduction. Richard Dawkins (1989) conceived of the meme as a replicator in the cultural and cognitive context. The neme is a replicator in the context of complex creative systems (Nieto-Gomez, 2016) that are organically evolving, transforming, and reshaping themselves, reproducing the recursive evolution of conversations, debates and concept creation.

An organization is a complex creative system that can be represented as the flow of data which transforms into information. It is this flow of information, not the organization chart, that defines the way an organization works. Now we live in a new world of torrents of data as a result of the Internet of Things (IoT). In fact, information often changes in the time it takes to verify it. As a result, many of our traditional organizational structures are breaking, especially those based on hierarchies. Yaneer Bar-Yam, President and Professor at the New England Complex Systems Institute, has noted,

A group of individuals whose collective behavior is controlled by a single individual cannot behave in a more complex way than the individual who is exercising the control (Bar-Yam, 2002).

This is why traditional command and control organizational structures are failing. The top-down model cannot cope with the level of complexity of the society around us. Nemetics aims to help organizational leaders in the following ways (Gallon, 2015a, slide 13):

- Provide a Leadership decision framework to resolve ‘wicked problems’ and improve performance.

- Act as a discovery tool to make sense of reality and view it in terms of interactions & emergence to help us strategize.
- Be a design tool to improve any particular situation in life. It might be personal, organizational or technical.
- Act as an enabler to observe one's own thinking process enabling possible change in individual and collective consciousness.

The distributed, self-organizing management systems that have been evolving over the last years correspond closely with the fragmented representation found in transmedia structures. Just as material emerges on different platforms and in different media according to the needs of the content and activities represented in transmedia objects, leadership roles and team configurations emerge in times and places according to the needs of the moment in an organizational structure. Nematics provides an ontology that allows us to make the distinctions necessary to organize highly fragmented big data into useful information, and follow the emergences of different self-organizing teams, tasks, and needs. Under this paradigm, a set of fractal analogies can be derived for studying organizational co-creation and collective resonance. Organizations need to become more consciously proactive in developing distributed leadership as the only way to cope with, and manage, complexity. Nematic thinking can help make the kinds of transitions needed, for example, to move hiring practices away from seeking profiles suitable for a given task, toward finding a mix of profiles that bring a variety of competencies and personalities together in a way that will foster teamwork and allow leadership to emerge as naturally as possible. Teamwork built around diversity requires more debate and discussion than ever, and neme sequences are vital in both planning and analyzing exchanges so that they can be as efficient and productive as possible.

Emerging experiences can be identified by studying interaction sequences, exchange paths, and conversational structure in augmented communication situations. Nematic research is the result of users from different fields and communities creating a common code for exchanging explicit information, implicit organizational knowledge, and meta-analysis for common research. Nematic strategies have been used in Barcelona (Catalonia) to explain social media dynamic flow to educators (Lorenzo, 2015, slides 22-23), in Cracow (Poland) to propose solutions for solving some of the wicked problems technical communicators have to face (Gallon, 2015a, 2015b) and in the New Delhi Area (India) for engineering training courses on vibration analysis and condition based maintenance (De, 2017, slides 9-12). From theoretical development to practical application, nematics evolves inside transmedia ecosystems as much as it is used to analyze them.

Case Study

The creation of the International Nematics Institute is itself an interesting example of a nematic process that was the result of collaborative interaction in the transmedia sphere with proactive intentions. A full discussion can be found in (Josefowicz, Gallon, & Lorenzo Galés, 2018).

A more recent example is the case of the Printernet organization. At the time of this writing, Printernet has existed 14 months. It is an informal global network of social enterprises. Using only Facebook, Twitter, and shared Google applications, this network has developed nodes in five African villages: two in Uganda, one in Malawi, one in Burundi, and one in Nigeria. Each is now earning some money on the way to sustainable self-sufficiency. The path to self-funding is publishing a magazine to be printed and distributed in each country, earning its income by selling advertising and attracting sponsors.

The project is using a nemetic strategy that involves moving information from bounded networks in North America and Europe to bounded networks in each village. Money is both energy and information in the sense that it clearly communicates that something can be done. The monetary exchanges used to launch the Printernet also serve to build the trust necessary for smooth information flow.

Nemetic Inward Transformation

The genesis of the Printernet in Africa came by “synchronicity” – the happy confluence of synchronicity and serendipity (Robertson, 2011). A chance encounter on Facebook between Michael Josefowicz (one of the authors of this article) and Jonas Fedweck, who organizes a volunteer group in Malawi, initiated the process. During the ensuing conversation Jonas did not ask for money, he asked for help building his social network.

After a week of conversation Jonas told Michael he planned to do a celebration for his volunteers who had been together for nine years. Michael then started a Facebook fundraiser to raise \$150 for t-shirts for the celebration. Joseph posted a picture of the volunteers wearing the t-shirts with a story of the positive affect on his group of volunteers (Notice phase). That process created the beginnings of a trust-based relationship. Jonas trusted Michael to follow through on caring. Michael began trusting Joseph when he saw the pictures to demonstrate the money had been used as it was said it was going to be used.

Continuing the conversation Michael suggested doing a poster to be distributed in the village to encourage people with AIDS to call people in the village who can help them to live a good life (Engage phase). Joseph and Michael collaborated on a design brief. After the design brief was complete, Michael used Twitter to connect with people in the printing community who gather under the #printchat hashtag. “Does anyone know a designer who would like to design a poster to do some good?” with a link to the design brief (Mull phase).

Within a couple of hours, a designer in Portugal tweeted back “I would love to do this project.” Two days after that a tweet with a link to a Google doc was sent. After discussion and review by the concerned parties, the PDF was emailed to Jonas. In three days, it was printed in Malawi and distributed to the village. They received 22 phone calls. Jonas posted a photo of the poster in the village (Exchange phase). Trust increased.

These processes increase trust with every iteration, and involve new people from other countries thanks to social networks. The demonstrated accomplishments encourage other participants to join the network.

Nemetic Outward Transformation

This same approach was used in what can be said to be the lead example, Uganda, where Joseph Atwongerie started a “Printernet Cafe” in 2018.

A Printernet group existed in New York, interested in finding alternative, less costly and more responsive ways to produce printed books and periodicals in the digital era. Joseph, in Uganda, connected with Michael in New York via Facebook, looking for support for his village tree-planting initiative:

1. The bounded network that is Printernet New York awarded a startup grant to trusted actors in the villages. It was used for WIFI infrastructure, 2 computers, an Internet connected TV and a desktop printer. Once in place it was called a Printernet Cafe. Naming the facility created a boundary around the networks composed of the people who used it. It became possible to say that a person was within that boundary or outside that boundary.

2. The Printernet Café starts earning a profit, selling computer time for 25 cents an hour. In June of 2018 it offers three-week computer skills classes for \$19. Following the principle of money as energy and information, it takes diverse small sums from around the village and transforms it by concentrating it. Once concentrated, it is redeployed to support tree planting, computer skills training, and micro loans to village people. This process is now extended to the other participating villages in Africa.
3. Throughout the growth period, Printernet New York provides daily consulting service via Facebook. The consulting approach was to break information into chunks (sometimes referred to as “molecular information” or “microcontent”). The chunks are communicated in just the right form at just the right time. All the decisions on the ground are made by the villagers. The motto of the consulting is “We advise, you decide.”
4. Printernet partners become paid reporters. They communicate information in the form of words and pictures on a regular schedule. The content is accumulated on a website. Stories from villages in Africa written by villagers in Africa are a unique value proposition for a magazine to be published from New York. The magazine will earn money by selling advertising. The profits earned will be distributed back to the villages.

Results Analysis

Both cases provide examples of nematic organizational sequences that not only function to demonstrate how information is activated but how the nematic sequence can be used for planning.

In one year, the Uganda Printernet cafe has a steady profit of \$500 a month after salaries and rent. It has seven computers and its income has been stable for 6 months. Sixty percent of the profit is used to support a program of planting the next 730,000 trees towards a goal of 1,000,000 fruit trees planted in the village. Thirty percent of the profit is used to give micro loans to villagers.

The Malawi group is transforming energy by pulling together volunteer labor. They have been transforming information resident in the volunteers to create more energy. The first intervention of the t-shirts gave them a sense of belonging to a team, not just a group. As the boundary became clearer, the energy within the boundary was augmented in the form of team spirit and the pride of being on the team.

Similarly, the Uganda group is a bounded network of volunteers who were organized to work to plant trees before Printernet became involved. Once the Printernet Café was in place, the boundary became more clearly defined. People used the cafe or did not. The cafe offers the immediate value of computers and internet access.

The term “boundary” or “bounded network” should not be seen as exclusionary. The boundary serves to identify a defined network, which members can join or leave freely. Their joining or leaving is largely defined by their participation in the various exchanges that take place inside and between networks.

The various Printernet partners also exchange amongst themselves, creating a network of bounded networks, in which best practices and problems can be explored. The global process produces a self-sustaining positive feedback loop that will grow organically.

Current Hypothesis

The Printernet case shows us how leveraging a small amount of energy (in the form of money) and information within a series of bounded transmedia networks can trigger a process of self-organization and organic growth. The project calls upon a multiplicity of platforms (Facebook, Twitter, Google apps)

and media (social networks, real-time and time-shifted messaging, printing, telephone, t-shirts) in an organic way. This is to say, the intention was not to use transmedia or to develop transliteracy skills, but rather to organize groups in the service of capacity building in poor countries, and social justice in rich countries. Doing this required a transmedia approach.

The same nemetic mindset and process can be applied to any organization, from businesses to government to education, social organisms, associations, and beyond. Each organization has its own aggregate of bounded networks. In the customer (or user) facing bounded networks members have the power to make fast decisions based on immediate context and conditions. The overwhelming majority of problems can be solved within the customer facing group. In addition to solving problems quickly, they can be solved while they are still small. It simply requires a maximum of decision-making power to be at the level of customer service work groups.

By extension, each level of management has the same power to solve problems at their level. Using the power of transmedia they can build a space where they act as internal consultants - give advice, be sensitive to risk, discuss the best ways to mitigate risk. All while having enough time in the day to:

- Notice the situation
- Engage (only) when necessary
- Mull the granular details of the situation at hand
- Exchange in the form of doing just the right thing at just the right time in just the right form.

FUTURE RESEARCH DIRECTIONS

In organizations, Nemetic Analysis of transmedia spaces helps detect strengths and weaknesses of internal teams and external networks. The two Printernet examples in the case study show clearly how nemetic structures can be used both to drill down deeper into an organization or community, and to expand connections out to include new partners. Where human-to-human and machine-mediated interaction take place, future researchers will need to develop adequate transmedia literacies and skills to explore these new relational situations, both in personal and professional environments.

New research focused on information flow in institutions and administrations can help professionals understand the emerging communication systems in complex environments, and to design formal and informal transliteracy learning for individuals and teams. Several action-reflection itineraries can be developed, in formal and informal training, for improved efficiency in identifying leadership, team dynamics, and coordination applied to transmedia communication.

Future benefits will come from applying results to personal and professional fields that are now emerging in the hybrid physical-digital environment:

- Interacting with wicked problems (favoring useful and valuable emergences from inherently chaotic systems)
- Designing and planning organizational action (using big data to adapt social behavior)
- Integrating gamification into professional fields (creating new transmedia spaces)
- Aggregating expanded connections and Internet of Things (new kinds of transliteracies)
- Relating personally and professionally to wearables and bionic implants (facing ethical and moral issues in collective debates)

- Developing lifelong learning environments (activating and moderating MOOCs, eLearning platforms and mLearning communities)

These lines of research tend naturally towards the creation of a transformation society, where new global competencies for leadership and organizational development are deployed to produce self-emerging collaborative initiatives that include transmedia learning environments. Examples such as the creation of the Printernet are useful to tell the story of transliteracy emergence and transmedia evolution and develop an academic corpus for integrating both transmedia and transliteracy into the communicative disciplines.

KEY TERMS AND DEFINITIONS

Complex Creative Systems: A subset of complex adaptive systems, which are systems in which a perfect understanding of the individual parts does not automatically convey a perfect understanding of the whole system's behavior. In a complex creative system, such as the rapidly evolving landscape of technological innovation, neither creative nor adoptive paths can be rigorously predicted, due to the high number of interlocked interactions among its components. It results from the non-linear interaction of the creative agent with users (intellect), objects (components), and contextual rules (regulation, social convention, human nature, etc.).

Intertext: A coherent text that shows a relationship to one or more other texts, where "text" is understood to mean any type of communicative content, typically forming a connected piece of work (includes images, sounds, video, etc.).

NEME: Mnemonic acronym for the fractal learning process of complex creative systems: Notice, Engage, Mull, Exchange.

Nemetics: A fractal code, evolved into a meta-language to facilitate communication among researchers in different disciplines in order to debate about complexity.

Synchrodipity: The compound interaction of synchronicity and serendipity, to produce a sense of discovery, delight or well-being, and a sense of connectedness between people, ideas and actions, derived from the flow and the interconnectivity of all things.

Transliteracy: The ability to read, write, and interact across a variety of communication tools, media, and platforms, from text, orality, signing or drawing, through handwriting, print, TV, radio and films to electronic networks and social media on digital platforms. It is a necessary complex skill for receiving, interiorizing or producing Transmedia.

Transmedia: Complex communication interaction based on multimedia, multimodal, multiplatform, intertextual human communication, in which each medium or platform has a distinct role to play in communicating the complete content. This interaction acquires meaning with each participating element by rebuilding the fragmented discourse.

Wicked Problem: A problem that is difficult or impossible to solve, because of incomplete, contradictory, and changing requirements that are difficult to define, identify, or recognize. It often involves stakeholders who have radically different worldviews. In addition, complex interdependencies make it so that the effort to solve one aspect of a wicked problem may reveal or create new problems.

The Organizational Culture in the Days Post 9/11: A Critical Insight

University of Palermo, Buenos Aires, Argentina

INTRODUCTION

Doubtless, terrorism has posed as a major threat as well as a great challenge for the US and Europe (Dershowitz 2002; Sloan 2006). As Jean Baudrillard puts it, terrorism not only signified more than a humiliation for the West but also “the mother of all events” (Baudrillard 2013). If terrorism probed something, it was that the urban spaces exhibit fertile grounds for potential attacks. People are more vulnerable in the urban cities or when they travel to work while the mass means of transport are often weaponized against civilian targets. In his book, *The Clash of Barbarism*, Gilbert Achcar says that terrorism opens the doors for a “narcissist commiseration” which means a sentiment of empathy for the first world victims. The global periphery, which was historically exploited by the center has the opportunity to feel closer to its oppressors (Achcar 2015). What is particularly clear is that victims have no same worth. While the victims of 9/11 were enthralled as “martyrs” thousands of others, located in the Global South, die or agonize day by day without any type of attention (Zizek 2008). Korstanje & Tarlow (2012) studied more than a dozen of plots in horror movies. They hold the thesis that English speaking travelers are marked as “special agents of civilization” who are targeted by evil-doers, monsters even terrorists who hate them. This is particularly interesting since the plots continue a much deeper narrative which was based on the sentiment of exceptionalism that historically characterized by the US. The American ethnocentrism toys with the belief that English speaking nations situate as more educated, more tolerant or even efficient than other cultures. Terrorism reminds not only this (the Anglo supremacy), but why the world, which becomes a dangerous place, should be pacified.

To date, a prolific number of books, studies and work-papers emphasize on the economic effects of terrorism in a macro-level of analysis (Chen & Siems, 2004; Abadie 2006; Benmelech, Berrebi, & Klor, 2010; Abadie & Gardeazabal, 2008; Giroux 2015), whereas less attention is paid to the micro-sociological changes introduced by terrorism in the working conditions. This chapter gathers two different ethnographies conducted in two Argentine companies. Centered on the previous studies of Luke Howie in Melbourne, we find interesting and contrasting outcomes which merit to be discussed. While interviewees acknowledge that terrorism is a major threat, they –instead- believe Argentina is far from what specialists dubbed as “The War on Terror”. In this respect, the different interviewed persons held that terrorism is not a problem for them, even he said “this is a problem of the Gringos!”. Lastly, we examine some of the published works that focus on the interplay of terrorism and working conditions to be contrasted to empirical validation. In the global South, i.e. Argentina, workers seem not to be affected by terrorism. Even, they forget that terrorism whipped Buenos Aires city on two occasions. One of the major problems faced by the applied research was the multiplication of quantitative-led publications

DOI: 10.4018/978-1-7998-3473-1.ch023

and information which obscures more than it clarifies. For that reason, we convene to make a qualitative study which straddles “the informational database or multi-variable analysis. In view of this, outcome cannot be universalized and only be strictly comprehended into the fields of the studied organization. It is our intention to provide new insights and methodological discussions revolving around the effects of terrorism in Latin America. In so doing, the theory of emotions and organizational culture occupies a central position. Because of time and space, the chapter does not cover all published works while it focuses on the Marxian tradition and the theories of Luke Howie.

BACKGROUND

Emotions are vital factors in the labor organizational culture. Arlie Hochschild (2002) writes that the founding parents of sociology have focused on emotions in different ways. From Durkheim to Weber, without mentioning Marx or Tonnies, emotions occupied a central position in the theoretical conception of solidarity. From its onset, sociology concerned about the social fact, as well as finding a credible answer that explains how society keeps united. For some reason, the evolution of the discipline through the twentieth century witnessed how “emotions” passed to play a marginal role in the sociological theory. In the threshold of time, as Hochschild observes, emotions set the pace to the advance of “rationality”.

In his book, *Politics and Emotions* Adrian Scribano (2018) lays the foundations towards a new fresh insight that helps understanding how liberalism manipulates emotions to protect the interests of the ruling elite. Through the articulation of different ideological artefacts, the global capital not only domesticates emotions –in the name of productivity and efficiency- but also the bodies according to an external stimulus. To some extent, sensibilities and politics are inevitably entwined. As Scribano puts it, the emotional factor is rechanneled and packaged to stimulate consumerism as well as the pleasure-maximization. In a hyper-competitive climate, each agent is in quest of its own happiness paving the ways to the rise of hedonism and individualism. In this respect, Machado Araoz & Pedro Lisdero (2018) explain that neoliberalism as a mega economic and cultural project arrived in Latin America to stay. Per their viewpoints, neoliberalism combined a set of negotiable with non-negotiable policies, which correspond to the needs of creating a space of stable governance. The dogma of precautionary principle, stability and progress act as a catalyst to avoid the social conflict which derives from decades of economic dependency and oppression. Based on the Marxian legacy, authors argue convincingly that neoliberalism –as a residual form of liberalism- mutates and evolves in different directions and shapes, but what remains in its ideological core is the “progressive reasoning” which means the instrumentalization and subordination of social relations in favor of the sense of efficacy. A Stolz (2009) focused on the elements that historically framed the liberal discourse. She found that the liberal reasoning shows how the loyalties of citizens are not given to the foreign policies of their states but citizens, rather, are systematically educated to believe they are “good boys” if taxes are paid, they vote or even leave their children in the school. This suggests that democracy does not consist in creating a climate of egalitarianism as the exegetes of liberalism think, but a spirit of conformity among citizens for the status quo to protect its interests. The Hobbesian conception of politics played a leading role to configure the doctrine of the state that redeemed individual liberty by the consensus of the majority. Of course, since the fear never disappears but it is enrooted in the core of politics, the legitimacy is commonly subordinated to the needs of securitization. The question of whether torture is accepted or neglected by electorship was widely discussed in the academic circles. While some scholars speak us of the “doctrine of lesser evil”, which suggests that legal torture can enhance democracy in the War on Terror (Ignatieff 2013), other

scholars believe that torture is only the peak of the iceberg of a much deeper repressive culture (Chomsky 2000; Altheide 2017; Korstanje 2018). The doctrine of the precautionary principle orients the present courses of action to protect homeland security but in so doing other unseen risks emerge. In retrospect, many of the resulted policies are based on misjudgments and biased diagnosis which obscure more than they clarify (Sunstein, 2005).

This begs a more than interesting question, whether our conception of risks may not be adjusted to reality, how can we cope with terrorism?

In his book, *The Challenges of Democracy in the War on Terror*, Korstanje (2018) affirms that emulating the tactics of conquest of the United Kingdom, which combined an internal climate of freedom with oppression and violence at the periphery, the US historically developed an imperial system orchestrated under the lemma, divide to rule. The different American governments not only adopted a negative viewpoint of the non-western “Other” but also feared the advance of non-democratic regimes (Korstanje 2018). Hence, Americans were certainly entrapped in an atmosphere of narcissism presented them as special, different, invested by the divine mandate to export democracy and capitalism as the best of feasible worlds. The American expansionism, doubtless, was historically associated with the idea that there is “rogue states”, or “failed states” which some day will compromise the security of the US. This was what experts dubbed as “American exceptionalism” (Tyrell 1991; Skoll & Korstanje 2013).

Last but not least, Donald Pease (1987) deciphers the tension between patriots and their concerns once the US liberated from the British Empire. Centered on a hot debate between liberty and the tyranny of Great Britain, the founding parents devote their efforts to avoid to repeat the example of Britons. While the US did the best to forget its troubled past, the idea of a manifest destiny gave Americans a reason to continue as well as a sentiment of exemplarity which marked their culture from its inception. The sense of manifest destiny not only resolved the long-simmering conflict of a new-born nation with its empire, but also posed the hopes that democracy should be imported and emulated to the rest of nations. As a result of this, the United States coined a new paternalism which accompanied their ethnocentrism up to date. In this vein, S. Coleman (2013) held the thesis that American fundamentalism orchestrated the essence of religion with politics, alerting that the world is always a dangerous place. These new orders seem to be charged with the needs of reforming the world, expiating their sins by means of sacrifice and a renovated atmosphere where fear and grace converges. Americans and other Anglophones, especially those in Britain and the settler countries, Australia and Canada, have produced a culture of terror. That culture induces a generalized fear among the populations of those countries. With a focus on the United States, the ruling class has constructed a culture of fear that has evolved from the kind of fear associated with the anticommunist hysteria in the years following the Second World War and its predecessor Red scares to its current incarnation of the terrorism obsession (Skoll 2016; Altheide 2017).

In a seminal book, which entitles *Memory and the Wars on Terror*, Jessica Gildersleeve & Richard Gehrmann (2017) explore the different constellations revolving around terrorism in the United Kingdom and Australia. The 21st century has seen the rise of a new climate of geopolitical relations, where, following 9/11, terrorism became the highest priority for most established democracies in the West. In parallel, academics of all stripes devoted their efforts to expanding knowledge on terrorism, and over recent years the US has monopolized this knowledge production in terrorism fields. Hence, a book that considers the perspectives of other English speaking nations (specifically the UK and Australia) deserves attention. Continuing with the previous observations done by Samuel Huntington about the “clash of civilizations, Gildersleeve & Gerhmann agree that a long-rivaled sentiment of hostility between East and West can be traced to collective memory. The US-led invasions to Iraq and Afghanistan accelerated dormant violence which finally resulted in the formation of a more radicalized cell, the Islamic State.

Per authors, terrorism is nourished by a set of different distinguishable narratives which are encapsulated into the collective memory. In this token, Kevin Foster, examines the relationship between the mass media and military forces. Employing the example of the Vietnam War, Foster demonstrates how journalists echoed the reports of leaders, published fake news or simply gathered contradictory information. Foster argues convincingly that the role played by US journalists during the Vietnam War was mirrored in Australian reporting of the War on Terror, who often consulted top-ranking commanders in Afghanistan before going on air. Lastly, Kezia Whiting (2017) and Belinda McKay (2017) respectively deal with the influence of the Iliad in the Western conception of the war, and the instability of memory in Janette Turner Hospital's fiction. With a focus on children's trauma, McKay contends that the post 9/11 landscape contains a combination of an apocalyptic climate, where the end is near, and the possibility of empowerment of historically marginalized peoples. Metaphorically linked to the fall of Troy, we are reminded not only that one day the empire will burn, but that the psychological fear instilled by terrorism enables the rise of radicalized discourses that place democracy in jeopardy. McKay argues that, at least for some, 9/11 was an "unprovoked attack", which activated a just response to the enemies of democracy. The false memory is conducive to the needs of repetition in order for the trauma to be anthropomorphized. McKay calls false memory to those historical facts which are politically manipulated or tergiversated to rememorize an idealized landscape of the past. Society keeps united through the articulation of these false memories. The problem lies in the fact when the lesson of history is not correctly learnt the disaster recurs.

Terrorism and the Emotional Effects on Culture Organization

In a seminal book, which entitles *Terrorism, the Worker and the City*, Luke Howie (2018) explores the meaning of security, as well as the effects of terrorism on working conditions in the urban landscapes. In this respect, if the 9/11 probes something, it is that terrorists look to target workers to instill an extreme fear in society. Echoing Jenkins, Howie said that terrorists do not want a lot of people dying, they rather want a lot of people watching! Howie coins the term *Terror-work* to denote the interplay between the needs of witnessing and the substantial changes forced by terrorism in the organizational culture.

"I explore the meaning of human security, precariousness and vulnerability in organizational, managerial, city-dwelling and workplace settings. Working people, particularly those in major cities, have been preferred targets for contemporary terrorism. Life in the city has perhaps always been risky, but the post 9/11, post-Madrid, post 7/7 city is filled with witnesses and victims of terrorism going about their work and lives in routine, mundane and everyday ways – I argue that is the essence of terror-work" (p. 14)

Although 9/11 happened exclusively on 11 September of 2001, its durable effects not only persisted but also subordinated other similar events. As a "mother of all events" (citing Baudrillard), Howie agrees that 9/11 –and the successive attacks in London and Madrid- opened the doors towards a "spectacle of terrorism" which imposed an ideological message to workers. In a hyper-mediated society, as Howie adds, the psychological fear experienced in urban cities does not correspond with the real danger terrorism poses. In Melbourne (Australia), days after the 9/11, higher levels of anxiety and uncertainty surfaced. Although the 9/11 involved directly New Yorkers, Australians believed that it was extremely probable a new attack takes places in Australia. Howie explains this writing that witnessing is stronger in distant places which have never been targeted by terrorism. Terrorism divides the world in two, victims which are the targeted workers and witnesses. While the former has been killed to cause political instability, the latter reinforces a much deeper logic of fear which voluntarily or not achieves the terrorist's goals. This point leads Howie to hold the thesis that in the name of the process of securitization, some material

asymmetries which are proper of capitalist system not only are far to be resolved but also are accentuated. While the status quo claims that security is the touchstone of the private sector, private security guards are left to low-paid salaries, extreme working conditions and excessive working hours. Paradoxically, those affect cities which were directly targeted by terrorism experience positive effects as an enhancement of social cohesion, but those which are geographically distant face higher levels of anxiety and angst. Among the perceived consequence of terrorism in working contexts we have the competence among workers, the rise of international conflicts, and the impositions of liberal economies policies otherwise would be rejected. The idea that the terrorist attack is imminent here and now ushers workers in an atmosphere of hyper-competition and mistrust where the man is the wolf of the man. Howie presents the compilation of seven stories of lay-workers in Melbourne, Australia. Their findings are at the best for us illustrative. A whole portion of interviewees agree what terrorism is but they are hand-tied to define it. Instead, they systematically evoke images and discourses circulating the public opinion just after 9/11. Besides, the possibility of an imminent blow in the Australian soil was a second stable element in all answers. This activates a witch-hunter against Muslim communities in the different Australian cities. Nonetheless, the fact that the masses turned duped once subject to the action of media sounds absurd to Howie. Instead of the classic Marxist studies which focus on the ideological power of terrorism, he said “the audience is the real expert of terrorism” because they feel its effects under their skins. Howie goes on to write:

“People in organizations can become paralyzed by fear and an obsession with eliminating all risks, dangers and threats. These obsessions are leaving visible and social traces. Suspicion, hostility, and angst have become commonplace in the world’s cities and organizations in times of terror. The Twin Towers were once a symbol of power, prosperity and corporate affluence. Their destruction has forced a new view of the proud and tall city-building –they represent impotence and fear” (Howie 2018: 168).

His point is very illustrative here. The city, as a social construal, exhibits not only a type of protection for city-dwellers but a cage, in view of the fact that workers follow standardized behaviour; and of course, stereotyped behaviour terrorists know very well. The city is not only a laboratory for terrorists but a fertile ground to target workers.

In the opposite, Geoffrey Skoll (2016) offers a contrasting explanation about the same issue. Terrorism validates, packages and disseminates an ideological message oriented to affirm the exploitation of lay-workers in favor of the ruling elite. Based on the idea that administrations govern through the creation of external and internal risks, Skoll alerts on the fact that fear is not caused by terrorism. The psychological fear, as well as the climate of insecurity, rest as the touchstone of Western capitalism. Following the Hobbesian dilemma, he toys with the belief that once capitalism expanded to the world its internal fear was disseminated in other non-western cultures with the same intensity. The global empire the US created cannot be sustained without the manipulation of the fear. Far from changing the working conditions, terrorism seems to be an ideological artefact to accelerate work-force exploitation. We do not need to find the causes of global fear in the microsociology, but in the material forces created and unfolded by the capitalist system. While the American capital adventured to colonize new worlds a much deeper sentiment of fear was successfully internalized by the natives. The success of the message consists of making the native believe they will live in the best of feasible worlds. For the American cosmology the World is an insecure place, fraught of despotic governments which are the cradle of evil-doers, terrorists and other enemies of democracy. Since America was a success cultural project which merits to be exported to the uncivilized world, local natives are interrogated to know in what side of the history they want to be. The world is divided into two: developed and under-developed nations, democratic or undemocratic cultures. The non-Western “Other” is often depicted as a person who is in the incorrect side of the river, while fear allows capital reproduction. As Skoll puts it, the rul-

ing elite keeps its privileged position in view of two combined elements: repression and ideology. The 9/11 established a mechanism of total control where individual rights were systematically subordinated to the idea of collective well-being. Not only obtrusive methods of surveillance were imposed but also on behalf of security the democratic institutions were seriously harmed. The allegories and discourses revolving around terrorism and 9/11 impede the concrete steps in changing the financial conditions that led the capitalist world to bankruptcy in 2008. In this point, Skoll and Howie converge. Terrorism in general and 9/11 in particular generated a type of new spectacle that places democracy in jeopardy. The divergence, doubtless, rests on the fact while Howie considers terrorism recreates the universal conditions of operation through the media even in the global South, Skoll adheres to the thesis that the culture of fear is enrooted into English speaking countries.

Having said this, terrorism activates a sentiment of exemplarity and exemption which was culturally enrooted in America since its early life. Over the recent years, some voices have questioned the role of the US as the watchdog of democracy in the world. The dilemma seems to be that while the US protects democracy in the four continents, human rights violations repeatedly occur in the Supermax prisons and other terrorist detention camps (O'Brien, 2004; Roth 2006; Skoll 2016; Korstanje 2018).

Argentines and 9/11: This is a Problem of the Gringos!

Argentina has suffered in its soil two major terrorist attacks in 1992 and 1994. The first event happened on 17 March of 1992 in Buenos Aires city. 292 civilians were hurt and 29 died when a bomb blasted before the Israel Embassy. Two years later, a new attack involved AMIA (Argentine Israelite Mutual Association) killing 85 persons and injuring more than one hundred civilians. Despite the virulence of the attacks, less is known respecting the responsible of the two successive attacks. Though some voices alert that The Republic of Iran was involved in the events, to date there is no domestic connection that reveals further information.

This section is based on my own ethnographies conducted during 2005 and 2013 in two companies. Because of confidentiality, the real names of companies, as well as interviewees remain covert. Company A is fully dedicated to the organization of tours and inbound tourism while Company B associates to computer security. I took an appearance in Company A on the morning of July and presented myself to the CEO (Charles 59 years old). Charles shortly introduced me in his role as organizer of the culture, as well as the protocols and main activities of his firm. Charles doubts that 9/11 would be a major threat for Argentina though he confirms the country went through two terrorist attacks in the pastime. Instead, he holds “este es un problema de gringos- this is a problem of the Gringos!” denoting some indifference for the sad events of 2001. He said that the US has historically served as a watchdog imposing restrictive policies and meddling in the autonomy of other nations. 9/11 was for him a “blow-back” for the intromissions in the Middle East. Charles finally shows some critical thinking about the foreign relations of the US. As he said “after Hiroshima and Nagasaki we saw how the world was divided in two poles. For this the US has never asked for pardon. They never recognized this was a horrendous crime. Do you believe this was on behalf of democracy?... (just after a silence of second he replied) “9/11 the US faced a great shock but most probably this is part of the costs of being a super-power”.

Charles introduces me to Sandra, one of his secretaries. Sandra (35 years old) is married and has two children. Instead of Charles, Sandra feels extreme empathy with the victims of 9/11. She even understands that the radicalized mind of terrorism appears to be “irreversible” and invariably it leads towards the formation of a hatred sentiment against Americans. Sandra recognizes terrorism is a major threat for the world, but to some extent not for Argentina. Her country was historically relegated from the World

and remains immune to terrorism. When I asked for the possibilities of a terrorist attack takes place in Argentine soil she responds

“no.. I believe that terrorism is not targeting nations in the Third World. We have other problems such as local crime, lack of political stability, poverty and higher rates of unemployment. I sincerely feel that the third world is not involved in the terrorist agenda. This is a problem of the established democracies since terrorists experienced psychological frustrations in their homelands. Terrorists hate western tourists because they hate democracy, in fact terrorism comes from the lack of political stability which is proper of undemocratic nations!”

Argentina has combined elected and de facto governments in its history. Sandra emphasizes this instability impeded the formation of firm democratic institutions towards a developed and sustainable economy. She is reluctant to the active role of the US and the different military interventions in the world. Sandra believes that the US involuntarily created the conditions of chaos and decontrol that today characterizes Middle East. At the time she is interrogated on the potential solutions to fight terrorism, she says that technology allows a rapid prevention of terrorist attacks as well as an efficient psychological profile investigation. After years of isolation, Argentina needs to be reinserted economically to the world, but in so doing, terrorism would target the country. The unconditional support of former president Carlos Saul Menem to George Bush in the Gulf War prompted the attacks on Israel Embassy and AMIA in Buenos Aires city. As a form of retaliation, these events showed the importance to keep the neutrality in this global conflict.

Different is the case of Fabian who works as a tour leader (travel agent). He loves traveling to New York and Chicago, as well as other American cities. He fascinates the American way and the prosperity of the global North. When he travels, further concerns on the fact of being targeted by terrorism surfaces. Instead, he answers that Argentina is far from being a real target for international jihadism. Fabian is fluent in English and feel empathy for Americans. This sentiment of empathy led him to experience a vicarious trauma just after 9/11. This ideological position accompanied him over months. As he replies, “tourism reconnects the world placing divergent culture in the same sphere of existence. Travelling is a great experience, a point where you learn from others. The act of killing tourists not only is horrendous but a sign of barbarism”. Terrorists are cowards who vulnerate lay-people who want to know other cultures. Doubtless, we need to fight against the intolerance of terrorism. Tourism is an activity of peace which prospers in democratic backgrounds.

In company B, I suspected, the results would be different but I got wrong. I did not have the opportunity to interview the CEO but I met with two executive directors: Robert (32 years old) and Benedict (59 year old). Surprisingly, both agree Argentina is not inserted in the battleground in the War on Terror. Hence, we are immune to terrorist attacks. Robert overtly said

“I work for a company of information security but learnt in my experience that security is a buzzword which depends on many factors. Much security we claim for, more insecure we feel. Argentina wont’s never been targeted by terrorism but also what happened in Israel Embassy is not our problem. This was not an attack against Argentina, this comes from an old problem for Palestine in the Middle East. I am sad for the innocent victims but strongly believe that this is a problem between Arabs and Jews”.

Rather, Benedict laments the Argentine government did not remind properly the events of 1992 and 1994. The attacks to Israel Embassy and AMIA have not left any lesson for Argentinians who remained indifferent. While the US government thematized the 9/11 as well as the struggle against terrorism as their most significant hallmarks, in Argentina the government coordinated efforts to hide “Jew com-

munity” relocating the embassy and AMIA. Beyond the suspicions, today authorities have no trace on the responsible minds managing the attacks.

FUTURE RESEARCH DIRECTIONS

The present chapter evinced some preliminary remarks on how argentine workers perceive terrorism. Although paraphrasing Baudrillard, 9/11 was “the mother of all events”, for interviewees do not feel terrorism is a major threat for Argentina. These findings contrast to what Howie presents in his study-case. Far from being concerned about terrorism, Argentinians strongly believe “this is a problem of the Others”, or at the best, “this is a problem of gringos!”. Secondly, terrorism is wholly perceived as a problem derived from psychological resentment. The third world, in this vein, would be a fertile ground for the process of radicalization terrorism needs. The hate against foreign tourists epitomizes a much deeper resentment against democracy. Those who work in tour organizations or serve as travel agents feel ideologically closer to the US and its War on Terror than other interviewees.

CONCLUSION

After further review, the interviewees consider uniformly that the two attacks in 1992 and 1994 were not directed to Argentina but to the State of Israel. Moved by the ongoing conflict in the Middle East, these attacks were the results of durable disputes between Jews and Muslims. Though the sample was not statistically representative, the obtained outcome reveals interestingly two important things. On one hand, terrorism created a mythical allegory revolving around 9/11, which subordinated the interpretations and meanings of other similar events. The attacks to Israel Embassy and AMIA were not only hidden, relocating the vulnerable “Other” in another geographical area of Buenos Aires, but they were understood through the lens of American exceptionalism. On another, terrorism shows concrete effects and consequences on the organizational culture, which can be deciphered using qualitative methods. Since the information gathered in these micro-units is not enough to be extrapolated to all Argentina, further research should be done. Our intention aimed at describing the position of some argentine workers –not the entire universe- before terrorism and other global risks. The chapter follows a descriptive dynamic which escapes to the monopoly and rationality of “quantitative-related methods”.

KEY TERMS AND DEFINITIONS

Conflict: A situation of dispute between two or more parts where each side follows different interests.

Labor Relations: A field of study which connotes the social ties and relations of workers and capital owners in the productive stage.

Terrorism: The illegal use of force or coercive violence to create terror or political instability.

War on Terror: An international military campaign that was started by the US and its allies just after 9/11.

Witnessing: A process accelerated by terrorism where the audience become trapped in the culture of terror.

The Diversity Paradox

2

J. Jacob Jenkins

California State University, Channel Islands, USA

INTRODUCTION

The diversity paradox is an organizational emphasis placed upon one potential understanding of diversity which, paradoxically, deemphasizes alternative expressions of individual difference. An organizational focus on representations of gender, for instance, synchronously moves the focus away from sexual orientation; an organizational focus on representations of sexual orientation synchronously moves the focus away from age; and so on. This article explores *the diversity paradox* in more detail, including its background and six primary tenants: fractionated understanding, visible hierarchy, false attainment, neglected representation, diminished alternatives, and potential tokenism. The article concludes with recommendations for both researchers and lay leaders alike whom hope to cultivate healthier organizational milieu.

The diversity paradox is an especially significant phenomenon in today's increasingly diversified society. Perhaps nowhere is this phenomenon more salient than within the United States. The percentage of Americans who self-identify as white has been in steep decline for decades, and this diversification is only projected to continue in the coming decades. Today, approximately 60% of those living in the United States identify as white, 17% as Latinx, 12% as black/African American, 5% Asian, and 1% American Indian/Alaskan Native. Yet by the year 2055, the percentage white Americans is predicted to decrease by nearly 15 percentage points, resulting in the United States no longer having a single racial/ethnic majority (Pew Research Center, 2016). This trend in increased diversification is mirrored elsewhere as well – fueled by political alliances in the European Union, immigration policies in South America, international trade agreements in North America, and so on (Rice, 2010).

Despite the increased diversity in countries like the United States – or perhaps because of it – issues of racial/ethnic inequality continue to plague our world. This reality is evident whether measured by income inequality (Glazer, 2005), health disparities (Dillon, Roscoe, & Jenkins, 2012), education levels (Closson, 2010), or incarceration rates (Ward, Farrell, & Rousseau, 2009). For these reasons, it is more important than ever for contemporary organizational leaders and scholars to learn how to engage with culturally diverse voices, perceptions, and taken for granted assumptions. The diversity paradox contributes to this need for increased understanding by revealing specific ways that diverse members manage tensions and limitations, thus, holding promise for improved racial/ethnic relations within intercultural contexts, organizations, and society writ large.

BACKGROUND

The diversity paradox first emerged as a theoretical framework during Jenkins' (2013, 2014a, 2014b, 2014c) four-year ethnography of Central Community Church (pseudonym) – an intercultural congregation located in Tampa Bay's urban corridor. In reference to Christian Scriptures that depict a culturally

DOI: 10.4018/978-1-7998-3473-1.ch024

diverse body of believers (see Matthew 28:9; Acts 17:26-27; Revelation 7:9, New International Version), Central Community strove to “reflect and impact the specific realities of [its] surrounding community” (Jenkins, 2014a, p. 7). Thus, Central Community actively promoted diversity via church literature, congregational events, and communal outreach efforts. A majority of sermon topics addressed the need for organizational diversity, and the church’s website described itself as “a multi-ethnic community... transforming the world through Jesus Christ” (Central Community, 2015, par. 3).

After 48 months of fieldwork, which yielded over 300 hours of observations, 140 pages of notes, and 30 semi-structured interviews with organizational leaders and members, Jenkins (2014) found Central Community’s organizational emphasis on diversity to have several unintended consequences. Although admirable on the surface, the church’s limited view of diversity as physical representations of racial/ethnic difference was found to paradoxically diminish the opportunity for alternative expressions of individual difference (see Jenkins & Dillon, 2014). Minority members’ attempts to conform to Central Community’s white normative practices unintendedly resulted in forced assimilation and self-disciplining; consequently, the church’s emphasis on cultivating a diverse congregation actually served to limit possibilities of organizational life – a phenomenon hereto referred to as *the diversity paradox*.

The diversity paradox has since been observed in additional contexts across the United States, including both religious and secular organizations. A study by Santis, Graham, and Jenkins (2019) of Central Faith Church in the greater Los Angeles area, for instance, revealed a similar tension surrounding the notion of organizational diversity. Such additional studies not only evidence the diversity paradox’s prevalence, but also its potential to help inform a wide range of religiously and geographically diffuse settings.

PRIMARY TENANTS

The diversity paradox is shown to manifest itself via six interrelated tenants: (1) fractionated understanding, (2) visible hierarchy, (3) false attainment, (4) neglected representation, (5) diminished alternatives, and (6) potential tokenism. First, organizational discourses promote a *fractionated understanding* of what it means to be a diverse organization, resulting in a *visible hierarchy* of difference and the sense of *false attainment* among its leadership. Among organizational members, this false attainment results in *neglected representation* for certain minorities, as well as *diminished alternatives* for organizational life and an increased level of *potential tokenism*. The present section further outlines each of these six tenants in turn.

Fractionated Understanding

The notion of diversity has become a normative reference for many organizational leaders and members when discussing racial, ethnic, and cultural equality. Diversity is exalted by nonprofit and for-profit organizations alike as being a central priority (Bunn & LaCour, 2009), key source of strength (Richard, 2000), and present-future goal (Unzueta & Binning, 2010). As a result, many organizations go out of their way to publicize the value they place upon creating and maintaining diversity via advertisements, job calls, promotional materials, and formal mission statements (Kidder et al., 2004; Kochan et al., 2003). In 2001, the United Nations Educational, Scientific and Cultural Organization (UNESCO) went as far as to declare that “cultural diversity is as necessary for humankind as biodiversity is for the nature” (par. 12).

Despite an increased value and emphasis on diversity, however, its meaning is still not clearly defined among the general public (Bell & Hartmann, 2007; Unzueta & Binning, 2009). Such ambiguity affords

a broad understanding of diversity's potential role and definition: variations in age, gender, religion, nationality, marital status, economic income, education level, able-bodiedness, sexual orientation, political affiliation, or linguistic disposition, to name but a few (see Coalition for Cultural Diversity, 2010). Because of this broad range of possibilities, organizational leaders commonly focus on one potential expression of the term. Rather than embracing diversity's broad range of possibilities, they choose to extol one fractionated understanding (Mill, Pinnegar & Polunin, 2007).

Originating in the field of chemistry, the term *fractionation* initially referred to the separation of an isotope into smaller quantities (O'Neil, Clayton, & Mayeda, 1969). Fractionation has since been used as a theoretical framework to describe the subdivision of large, complex concepts within social science into smaller, more palatable ideas. Thus, by subdividing an issue like diversity into smaller parts and focusing upon only one potential understanding, organizations are able to make sense of a potentially overwhelming topic. This process has also shown to alleviate the emotional load associated with resolving controversial issues, and to facilitate a better working relationship between organizational members.

Although useful in many instances, such a fractionated approach to diversity is problematic because it inherently neglects opposing perspectives. Jenkins' (2014a, 2014b, 2014c) and Sabrina, Graham, and Jenkins' (2019) aforementioned studies of Central Community and Central Faith respectively found organizational leaders to value difference; yet as a result of their fractionated understanding, they each expressed this value exclusively through differences in race/ethnicity. This reality was evidenced via racially/ethnically diverse band members, promotional materials featuring stereotypical phenotypes, and even frequent challenges by the lead pastor of Central Community for congregational members to interact with others who "looked different" than themselves. Thus, organizational leaders within both Central Community and Central Faith came to overlook alternative conceptions of diversity. Such a fractionated understanding also discounted the way differing expressions of personal identity intersect with one another (i.e., intersectionality), while simultaneously creating a visible hierarchy of difference.

Visible Hierarchy

A fractionated understanding of diversity commonly results in the valuation and devaluation of particular types of difference. In the same way that organizational metaphor inherently emphasizes one insight while simultaneously deemphasizing others, an emphasis placed upon one aspect of diversity simultaneously deemphasizes alternative aspects. As Hamburger and Itzhayek (1998) write: "Metaphor... determines the way people perceive, remember, and analyze information they receive. However, any single metaphor limits people's perception by blocking and distorting the information encountered... They are like people speaking in different languages" (p. 383). Hence, by focusing solely upon one understanding of diversity, organizational leaders can come to view this form of difference as being more valuable than other potential forms.

This visible hierarchy created by *the diversity paradox* typically serves to elevate visible manifestations of difference within a given organizational context. Said differently: organizational hierarchies of difference are usually based on physical and visual representations of racial/ethnic diversity (a.k.a., *marked bodies*). This emphasis on visible representations of race/ethnicity seems due, in part, to external differences being the easiest forms of diversity to observe and quantify. Phenotypical markers such as skin color and hair texture can be confirmed at a distance, in a matter of moments, and without the need for personal interaction. Alternative expressions of difference, such as nationality or linguistic disposition, are much more difficult to detect and require a greater investment of both time and energy. As a

result, these unseen markers of diversity are commonly devalued within organizational discourses – or else overlooked entirely – resulting in a false sense of attainment among its leadership.

False Attainment

By communicating a fractionated and hierarchal view of diversity, organizational leaders not only tend to perpetuate a limited conception of this term, but also decrease their ability to recognize ways in which this understanding actually renders their own organization less diverse. Although a relatively equal number of men and women attended Central Community, for example, its leadership was entirely male (Jenkins, 2014a). This reality was echoed in the later study Central Faith outside Los Angeles (Santis, Graham, & Jenkins, 2019). Despite such lack of diversity, the leadership staff of both congregations remained convinced of their organizations were in fact diverse. Thus, the inability for Central Community or Central Faith to fully recognize or value alternative expressions of diversity resulted in a false sense of attainment among its organizational leaders.

Taken one step further, Jenkins (2014b, 2014c) and his colleagues (Santis, Graham, & Jenkins, 2019) observed that the diversity paradox allowed leaders to celebrate and promote their organization's one-dimensional view of diversity through promotional materials highlighting race/ethnicity. Ultimately, such a false attainment of diversity can lead to several consequences commonly faced by minority members within organizational contexts – namely that of neglected representation, diminished alternatives, and potential tokenism – each of which serve as the diversity paradox's final three tenants.

Neglected Representation

As a result of fractionated understanding, visible hierarchy, and false attainment, *the diversity paradox* can also result in neglected representation for certain minority members. Such individuals might be allowed to fully take part in the organization outwardly; however, they are often not considered part of the organization's diversity quotient. As a result, they are not valued or celebrated in the same way as visually diverse members.

Although several minority participants in Jenkins' (2014a, 2014b, 2014c) longitudinal study of Central Community desired to hear more gospel music, for instance, music choice was not an organizational discourse used to measure diversity. DeYmaz (2007), a prominent leader in the Multi-ethnic Church Movement, characterizes variations in musical style as a "hallmark" of healthy intercultural congregations. Yet according to Central Community's leadership, changes in musical rhythm, tempo, song selection, or instrument choice would not affect its level of diversity; thus, grievances against such a "minor" detail as music were neglected by leaders and other members as merely personal preference. At other times, these grievances were seen as something worse: grumbles of discontent, and an affront to the organization's superordinate goal of creating a diverse organization (see Driskill & Jenkins, 2019).

Santis, Graham, and Jenkins' (2019) observations within Central Faith found similar instances of neglected representation, as leaders overlooked calls for alternative approaches to time management by adhering to a strictly monochronic understanding. Rooted in Western society and stemming from the Industrial Revolution, a *monochronic* view of time is defined by precise and regimented scheduling. By dividing time into precise units, it becomes a tangible commodity that can be "spent" or even "wasted," hence, the adage "time is money." In contrast, a *polychronic* view of time is less rigid and more fluid. It focuses on relationships over scheduling, and is largely associated with Asian, Arabic, African, and Latin American cultures (Cohen, 2004).

Because of Central Faith's adherence to a monochronic view of time, Santis, Graham, and Jenkins (2019) found congregational members were pressured to arrive on time for church related events – especially Sunday morning services. This expectation was evidenced by a digital countdown in the sanctuary used to mark the start of each service, the repeated suggestion by organizational leaders to arrive on time, and even the strategic use of musical guests to encourage punctuality. In the end, such a narrow focus on their monochronic view of time management inhibited congregational leaders from recognizing alternative possibilities of neglected representation – namely, alternative approaches to time management.

Diminished Alternatives

Because of *the diversity paradox*'s tendency to devalue and neglect unseen markers of difference, certain minority members are often unable to express their diverse views and approaches to organizational life. Hence, the organizational emphasis Central Community and Central Faith placing on visual and physical representations of race/ethnicity not only devalued alternative understandings of difference, but also devalued alternative ways of *being* (Jenkins, 2014a). Specifically, the value these organizational leaders placed upon visual representations of race/ethnicity devalued representations of female leadership, sexual orientation, able-bodiedness, nationality and linguistic disposition, as well as age, marital status, economic income, education level, and political affiliation.

On an organizational level, other potential examples of diminished alternatives include white normative approaches to service structure and choice of sermon topics. African American and Hispanic/Latino church services, for example, are usually longer in length than white church services, lasting as long as four hours (Nelson, 2005). In contrast, church services with predominately white members average a mere 65 minutes in length. In addition, African American and Hispanic/Latino church services typically focus the majority of its time on communal singing and dancing; white church services typically reserve a majority of Sunday morning for the pastor's sermon (Thumma, 2007). The choice of sermon topics also differs between predominately African American and predominately white churches. Stemming from the African slave trade and rooted in the Biblical account of Moses leading his people from bondage, African American congregations generally view salvation as the deliverance from present-day hardships and oppression: racism, financial inequality, institutional oppression, etc. Due to its emphasis on social and religious collectivism, Hispanic/Latino churches share a similar focus on the here and now. Conversely, white congregations generally view salvation as the deliverance from eternal damnation, focusing upon its spiritual and enduring dimensions in the afterlife, rather than its physical and temporal implications (Pinn, 2006).

Despite each of these potential alternatives, Jenkins (2014a, 2014b) and his colleagues (Santis, Graham, & Jenkins, 2019) found congregational discourses to be decidedly white in their approach to church processes and practices. Each service rarely lasted longer than 60 minutes. Services were also organized around the lead pastor's weekly sermon, and although the churches routinely focused on present day hardships and oppression within their local communities, organizational discourses still framed conceptions of salvation in strictly spiritual terms.

Potential Tokenism

Finally, via neglected representation and diminished alternatives, *the diversity paradox* reveals a potential danger for intercultural organizations to consign minority members to that of token status. First defined by Kanter (1977) during her study of gender representation in the workplace, *tokenism* is a perfunctory

gesture toward the inclusion of minorities within an otherwise majority group or organization. Such inclusion is typically used to create an artificial façade of diversity, while averting any potential accusations of discrimination (see also Kelly, 2007).

Kanter (1993) divides the process of tokenism into three categories: *heightened visibility*, *assimilation*, and *exclusion*. Token individuals are often appointed to highly visible roles within an organization, yet are granted limited influence or capacity for organizational change. Due to such heightened visibility, tokens commonly experience an increased level of pressure and expectation placed upon their personal performance. Meanwhile, the uniqueness of token individuals is often overlooked by those within the dominant group, resulting in their assimilation into one collectively inferior grouping, characterized by erroneous and exaggerated stereotypes. Tokens often accept these flawed stereotypes for fear of exclusion, yet feelings of isolation and segregation are still commonplace among token individuals.

Consistent with Kanter's (1977, 1993) characterization, *the diversity paradox* reveals a risk for tokenism within intercultural contexts because of the possibility for organizational discourses to become focused upon one specific (and visibly apparent) view of diversity. For this reason, the mere presence of organizational members whom fulfill that view could be interpreted as enough to "satisfy" an organization's diversity quotient. Furthermore, these members run the risk of being made highly visible within the organization, while simultaneously granting those same members limited influence or capacity for organizational change.

Understood in yet another way, *the diversity paradox* also reveals the potential for the phenomenon of *attributional tokenism*. That is, a garish emphasis placed upon one particular trait of an organization's culture, norms or practices that promotes a desired image or appearance, while overlooking cultural norms and practices to the contrary. As a theoretical extension of tokenism, attributional tokenism does not grant any particular person or persons that of token status, but rather a particular organizational feature or characteristic.

Attributional tokenism is not limited to the notion of diversity, nor is it limited to intercultural contexts. Rather, this concept can be recontextualized to any number of organizational settings. It can pertain to any organizational quality or idiosyncrasy of an ambiguous and indefinite nature. If an organization seeks to appear "innovative," for instance, leaders and members might emphasize one inventive feature of the organization (e.g., its dynamic office design), while deemphasizing a multitude of other organizational features that remain utterly conventional (e.g., its dress code, salary schedule, hiring process, promotion procedures, management structure, advertising and growth strategies, etc.). Similarly, if an organization seeks to be perceived as "desirable," it might emphasize its high number of employee applicants, while deemphasizing its exorbitant rate of employee complaints or turnover; if an organization seeks to be perceived as "youthful," it might emphasize the young age of its CEO, while deemphasizing the elevated age of its managers and employees; and so on.

The act of attributional tokenism is not inherently negative. It could be argued that *branding*, which has become a buzzword in personal and organizational development, is a form of attributional tokenism (see Lair, Sullivan, & Cheney, 2005). Howard Schultz, for instance, highlights the specific value of *brand awareness* (i.e., the ability for a consumer to recognize a brand under differing conditions) and *attitude branding* (i.e., the ability for a brand to evoke a particular emotion or sentiment). His observations also stress the ubiquitous nature of branding in contemporary society, as well as its ability to influence everything from fitness to coffee (Daye, 2006, par. 1). During Jenkins' (2013, 2014a, 2014b, 2014c; see also Jenkins & Dillon, 2012) and his colleagues' (Santis, Graham, & Jenkins, 2019) longitudinal studies of intercultural congregations in Florida and California, however, the organizations sought to be perceived (a.k.a., branded) as "diverse." As a result, organizational leaders were able to emphasize the

racial/ethnic composition of their congregations, while deemphasizing their organizations' absence of female leadership, as well as its complete lack of LGBT, disabled, international, and non-English speaking congregational members. Such a discursive move served to create a façade of increased diversity via attributional tokenism.

SOLUTIONS AND RECOMMENDATIONS

The diversity paradox highlights a need for intercultural leaders and members to recognize alternative expressions of difference. A broadened view of diversity would positively correlate with organizational leaders' and members' ability to express their unique views, perspectives, and approaches. Through a broadened understanding of diversity's potential meaning, additional alternatives for organizational life would also emerge, decreasing the probability of personal or attributional tokenism. A broadened understanding of diversity alone is not enough for lasting change, however, as the socially constructed categories of difference are ever-changing. For that reason, organizational leaders and members must also remain continuously receptive to understandings of diversity beyond those presently held by the organization and society at large. Rather than merely adopting a broadened view of diverse communities, intercultural organizations must employ an *ever-broadening* definition. In other words, an organizational view of what it means to be diverse must be viewed as ephemeral: fluid and ever-changing. Any formal or informal classification of terms like "diversity" must remain living documents, open to perpetual change.

In order to actualize such ever-broadening definitions, it is essential that organizational leaders and members adopt reflexive mechanisms of change (see Senge, 2006). *Reflexivity* is defined as the recursive turning-back of personal experience upon itself. Soros (1994) further characterizes the concept of reflexivity as a two-way feedback mechanism that helps shape the participants' thinking; in turn, the participants' thinking helps shape reality in a recurring loop (p. 2). Such a view of reflexivity draws obvious comparisons to the *observer effect* (Furuta, 2012) and *uncertainty principle* (Heisenberg, 1930), which illustrate the way certain measurements cannot be made without affecting the very object in question. As a theoretical physicist, however, Heisenberg dealt with external observations of complementary variables, while reflexivity deals with the role of cognition as a generative tool for observable phenomena.

Reflexivity is also embedded within – while drawing upon – our current perceptions of reality. In this sense, reflexivity is both a result and limitation of our communicative encounters with others: "Reflective understanding is an integrating process that draws upon understandings gained from the body's interaction with the world and from the accumulated wisdom of the culture" (Polkinghorne, 2004, p. 151). A researcher can only be understood in terms of those whom s/he seeks to research; those s/he seeks to research can only be understood in terms of the researcher. It is only together that we mutually specify our own conditions of existence, hence, reflexivity is "relational-in-a-context" (Steier, 1995, p. 64).

Due to its pensive and recursive nature, reflexivity is often illustrated as a set of mirrors doubling back on themselves. Like the Place of Versailles' great Hall of Mirrors, this recursive aspect of reflexivity can be visualized as an infinite set of loops that fail to reflect or generate anything beyond itself. Such recursivity has prompted certain scholars to disparage reflexivity for its narcissistic nature (e.g., Steier, 1995). Other scholars, however, have venerated reflexivity for its ability to challenge patriarchal knowledge production (Haraway, 1991) and its promise for social change (McLafferty, 1995). Pels (2000) further addresses this issue by offering a potential solution for contemporary scholars: "I...defend a view of reflexivity which I call 'one step up.' ... It ties just one loop, adds one level of self-exemplification, in order to bend the rectilinear story into a curvilinear or elliptical one" (p. 3).

By nurturing this reflexive, “one step up” culture among its leaders and members, intercultural organizations can learn to reflect-in-action upon organizational practices and structures. In the end, rather than merely addressing the organizational issues highlighted by *the diversity paradox*, such reflexive mechanisms of change will ultimately provide organizational leaders and members the ability to address their own faulty assumptions about the organization’s current level of diversity – or lack thereof.

FUTURE RESEARCH DIRECTIONS

Continued research on intercultural organizations is severely needed – particularly within racially/ethnically diverse congregations. The need for such research will only increase in places like the United States as its racial composition continues to diversify (US Census Bureau, 2008). Suggestions for future research include ethnographic studies of other racially/ethnically diverse congregations beyond Florida and California in order to identify additional manifestations of *the diversity paradox* – added ways in which an organizational emphasis on one potential understanding of diversity (e.g., age, gender, nationality, sexual-orientation, etc.) serves to deemphasize alternative expressions of difference.

Given that less than 8% of American congregations are intercultural (Emerson, 2008), future research should also extend this study’s focus to monocultural congregations. Rather than focusing on a racial/ethnic outliers like Central Community and Central Faith, organizational communication studies are needed to examine how religious leaders and members constitute community within homogenous populations. Similarly, future organizational studies should explore faith traditions beyond Christianity alone. Indeed, nearly two-thirds of the world do not identify with the Christian religion. An estimated 21% of the world’s population self-identify with Islam, 16% self-identify as “nonreligious,” 14% Hinduism, 6% Buddhism, and 6% Taoism or Confucianism (Central Intelligence Agency, 2013). In light of these numbers, and fact that Islam is also the world’s fastest growing religion (Zein, 2007), it is becoming increasingly vital for organizational communication researchers to examine the organizational complexities surrounding race/ethnicity within other religions as well.

Additional areas for research involve the intersection of community and race/ethnicity within secular contexts. Even though the majority of Americans attend church at least once per year and more than one hundred million Americans are involved in church to some degree (Emerson, 2008), these numbers indicate that approximately two hundred million Americans are *not* involved in a religious or faith-based organization. Consequently, it is vital to explore the way community is co-constructed and maintained by racially/ethnically diverse populations within nonreligious milieu: health settings, educational institutions, governmental organizations, etc. Research within these organizations is needed to identify manifestations of *the diversity paradox* within secular contexts as well.

CONCLUSION

The diversity paradox reveals the propensity for intercultural organizations to promote one potential understanding of diversity in a way that diminishes alternative possibilities of organizational life for certain minority members. This paradox has been shown to occur in six interrelated ways. *Fractionated understanding* refers to the way organizational leaders make sense of a potentially overwhelming topic by subdividing the notion of diversity it into smaller parts and focusing upon only one potential understanding. *Visible hierarchy* refers to the increased value organizational leaders routinely place upon

certain subdivisions of diversity, namely physical and visible representations of racial/ethnic difference. *False attainment* refers to the way in which leaders can become self-convinced of their organization's diversity – because of the increased value they place upon their own subdivided understanding – without ever considering the multitude of ways in which it is not. *Neglected representation* refers to the way certain minority members can be overlooked in regard to an intercultural organization's diversity quotient. *Diminished alternatives* refers to the way these members often feel unable to express their diverse views and approaches to organizational life, and *potential tokenism* refers to the risk of appointing minority members to highly visible roles within an intercultural organization in effort to create an artificial façade of diversity.

In light of the racial/ethnic inequalities that continue plague our world, it is vital that organizational leaders and members continue in their pursuit of building culturally diverse communities. Considering the ambiguous nature of diversity, however, it is equally imperative for leaders and members to remain mindful of the ways in which they seek to build those communities. Thus, *the diversity paradox* offers a theoretical understanding for how organizations can serve to stem racial/ethnic inequality in our world writ large.

KEY TERMS AND DEFINITIONS

Attributional Tokenism: A garish emphasis upon one particular trait of an organization's culture, norms, or practices that promotes a desired image or appearance, while overlooking cultural norms and practices to the contrary; a theoretical extension of *tokenism*.

Fractionation: The separation of isotopes into smaller quantities.

Marked Bodies: Physical and/or visually apparent representations of difference.

Reflexivity: The recursive turning-back of personal experience upon itself; the process of thinking about thinking.

Tokenism: A perfunctory gesture toward the inclusion of minorities in a group or organization.

White Normativity: A view of whiteness as the default culture in society; the unspoken norm.

Fab Labs: A Place for Innovation, Collaboration, and Creation?

2

University of Moncton, Canada

INTRODUCTION

In recent decades, innovation has become a central issue in the survival of public and private organizations. To meet this challenge, most of them are exploring new ways of organizing work, including seeking to build on the creativity of their employees. These explorations result in the invention of new forms of coordination and cooperation.

At the same time, job tasks and employment relationships have become more complex and diversified over time and need to be redefined (Paris and Lê, 2016). Organizations are also looking for ways to increase the innovative spirit of their employees and to develop organizational innovation (autonomy, versatility, development of collective actions, team work for example). This context contributes to the creation of new forms of employment and activities. To ensure these restructurings and these new expectations, new ways of organizing work are unfolding, which has helped to make it possible to implement fab labs.

BACKGROUND

Fab Labs are proliferating around the world and are presented as new places of collaboration and exchange open to all and in which anything is possible, but these places are more specifically oriented towards the fabrication of products with 3D printers in many cases, or other types of productions. In doing so, the place does allow for the creation of many innovations and facilitates meetings between creatives and designers. However, they can also create certain risks that are not yet necessarily documented.

In this chapter, the authors propose to draw up a synthetic and nuanced inventory of the benefits and risks created by fab labs. This assessment is therefore original, given the lack of research on the negative aspects of these places and the lack of contrasting studies on the subject in particular.

FOCUS OF THE ARTICLE

The Contributions Of Fab Labs: Between Knowledge Democracy And Sharing Of Tools

Fab Labs, Places Of Digital Democratization

Fab lab is the contraction of “fabrication laboratory”. Fab labs have been created within the MIT Center for Bits and Atoms to enable everyone to become the main players in technology manufacturing rather than just spectators (Gershenfeld, 2005). The first ever fab lab was established at the Massachusetts Institute of Technology (MIT) in the CBA (Center for Bits and Atom), a research laboratory founded in 2001 by the NSF (National Science Foundation). Thus, in the same way that the Internet has enabled the collaborative web and in fact the development of sharing tools, the CBA wishes to make fab labs the logical consequence of the digital revolution, by giving everyone the opportunity to manufacture digital tools, as Neil Gershenfeld, director of CBA attached to MIT (Scaillerez and Tremblay, 2017a and b) wishes. After participating in the digital revolution, MIT wants to democratize digital manufacturing. The Fab lab network, also initiated by MIT, has listed nearly 1,000 so far (Deskmag, 2017).

Fab Labs, Places Favorable To Open Innovation

The fab lab activity is part of the dynamics that can result from open innovation (Chesbrough, 2003 and Chesbrough, Vanhaverbeke, and West, 2006). This theoretical framework includes two main streams, the first dealing with the relationship of the concept with the use of internal skills of the company, the second dealing with external partners. Fab Labs can register their activity in this second stream of thought.

Open innovation refers to the idea that companies do not have all the skills needed to innovate internally. On the contrary, external resources, external research and development (R & D) can foster innovation in an organization. This theory of open innovation refers in a way to the work of Nonaka (1991), which also indicated that companies do not always have the best talents at their jobs, so they must seek to benefit from expertise and skills externally, including the tacit knowledge put forward by Nonaka and Takeuchi (1995). This does not mean that we must forget internal knowledge, but simply that we must also acquire intellectual property and ideas developed by others (Trott and Hartmann, 2009). It is also necessary to integrate into networks to access external knowledge, and this is where fab labs can be useful. In this respect, fab labs can then as much meet the needs of companies, as those of entrepreneurs and even anyone wishing to manufacture a material or immaterial object.

Trott and Hartmann (2009) point out that this idea of external knowledge is not entirely new but has been put forward less than internal talent as a source of creativity and innovation. Open innovation actions can contribute to the development or enhancement of a product or reflection through the use of external sources, such as the various actors associated with it (Chesbrough, 2003; Laursen and Salter, 2006). This is what we can find in a fab lab where users will take advantage of the community tools to build a prototype together. Everyone brings his skills. It is a sharing of knowledge and tools between creator and creative. In this case, open innovation relies on the intervention of external resources, but also of intermediaries (Chesbrough, 2006) with the ultimate aim of organizing the meeting between various users through the development of an innovative process. By following this reasoning, a fab lab can then be considered as an open space of innovation, drawing strength from the collaboration between its members.

Fab Labs, Places Of Sharing (Tools And Knowledge)

The existence of a collaborative environment is an important factor at the beginning of the innovation process whether you're in a small business or you're an entrepreneur, or a craftsman, because success or failure depends on their ability to acquire external resources and knowledge complementary to those available internally (such as their own knowledge or their own material). To justify its existence, a fab lab therefore requires the help of intermediaries, individuals or organizations serving as an interface between two or more parties throughout each stage of the innovation process (Howells, 2006; Fleischmann, Hielscher, and Merritt, 2016). Their role is then to try to develop a relationship of trust between the actors solicited, acting as matchmakers to encourage meetings and the sharing of tools and knowledge.

This can be done by:

- the use of resources in its possession (Chesbrough 2003; Leroux, Muller, Plottu, and Widehem, 2014), such as the pooling of 3D printers for example. In Montreal, in the area of innovation, Échofab is a fab lab that provides all (entrepreneurs, craftsmen, students ...) four 3D printers, a laser cutting machine or a digital milling machine. Amateur or expert creations are possible;
- the development of an environment designed to facilitate exchanges between members of the group, such as creating within the fab lab open working spaces, places of conviviality to take lunch together or coffee ...). In Quebec City, Chambre Blanche is a fab lab that welcomes artists from around the world and from multiple domains (dancers, sculptors, painters ...). To facilitate meetings between artists, or between manufacturers and creatives, Chambre Blanche organizes events such as Design Fiction nights. The fab lab also hosts artists who live on site and who have the equipment and workshop to provide an environment conducive to their creativity. It can also facilitate the flow of knowledge and meetings (Leroux and al., 2014; Fabbri and Charue-Duboc, 2016), by organizing workshops, discovery workshops, or all types of meetings between its users. In the city of Sherbrooke in Quebec (Canada), La Fabrique is a fab lab that sets up workshops to also allow its users to learn how to make many products.

A fab lab then seems to be a place where this intermediation is possible through a variety of factors facilitating the culture of collaboration within it and thus, allowing contacts to achieve the expected result, such as business opportunities or product or service innovations. These manufacturing spaces make available to all people (for free or at a lower cost) their machines and tools in order to lead to the manufacture of an object or digital innovations. They facilitate learning by doing and sharing skills (Bosqué, 2015). In short, in a fab lab, anyone with an idea can benefit from a place to test (prototyping), then create a physical or digital object freely and quickly, because the place provides the necessary means (Troxler and Wolf, 2011). In a fab lab, the cooperation can allow for example the creation of products with numerically controlled machines, such as a 3 D printer or a laser cutting machine (Fastermann, 2014; Allen, 2016; Fleischmann and al., 2016).

In short, fab labs are community laboratories that are conducive to exchanging knowledge and resources between various people in different professional fields such as the web, information and communication technology (ICT), as well as those of health, arts and sciences for example (Bosqué, 2015), or simply production of artefacts with a 3D printer.

Fab Labs, Places Conducive To The Collaborative Economy

Fab Labs are devices designed to facilitate exchanges, sharing and collaboration. Their action can then be considered as part of the new economy, particularly the collaborative economy, which relies on the sharing and production of common values and new forms of work organization (Botsman and Rogers, 2010). The collaborative economy indeed promotes collaborative lifestyles or collaborative consumption (Felson and Spaeth, 1978), as well as contributive production (digital tool manufacturing or 3D printer: Vak and al., 2015; Devendorf, De Kosnik, Mattingly, Ryokai 2016; Fleischmann and al., 2016) that can be found within fab labs. These new economic theories promote collaboration, pooling and sharing, which then serves as fertile ground for the establishment of third places. These contribute to the sharing of a space (co-working), a reflection (the living lab), but also tools (fab labs).

Within these systems, the collaborative economy can take various forms such as the sharing economy, the circular economy (Le Moigne, 2014) or the economy of functionality (Van Niel, 2015). These approaches and collaborative practices can then be seen as participating in this economy of frugality (Radjou and Prabhu, 2015), or even happy sobriety (also called voluntary simplicity, Boisvert, 2005).

In sum, in agreement with certain values of the new economy (McDonough and Braungart, 2011), fab labs are part of a broader desire to decrease (Sempels and Hoffmann, 2012), to combat planned obsolescence (Geldron, 2013) and challenge traditional neoliberal dogmas (Rifkin, 2014), given the need to reduce the impact of hyper-consumption on the environment. This new collaborative economy also supports the sale of the use of the good and not the good in itself in an ecological perspective and sustainable development (Gaglio and Lauriol, 2011).

At first glance, fab labs seem to bring a lot of benefits and are part of a modern trend to restore a certain sharing and democratization of knowledge. However, these places also include risks of deviance that must not be ignored.

RISKS INCURRED BY FAB LABS: BETWEEN DESKILLING OF KNOWLEDGE AND NEW OCCUPATIONAL RISKS

Fab Labs, A Risk Of Skills Disqualification

Fab labs are part of the do-it-yourself (DIY) movement (Kuznetsov and Paulos, 2010; Rognoli, Bianchini, Maffei, and Karana, 2015; Tanenbaum, Williams, Desjardins, and Tanenbaum, 2013). This DIY is often celebrated for the potential it holds for the democratization of knowledge, for the development of citizen-made manufacturing, for the empowerment of ordinary people and for its educational, economic and socio-cultural value (Wolinsky, 2009).

In addition to apologizing for a new way of “doing”, fab labs also develop ways to communicate, domesticate, “trivialize”, that is to say to make more accessible and democratic “do it yourself” movement. The DIY then embodies the sharing of data and knowledge, as well as the opening of knowledge gates hitherto reserved exclusively for technological institutions. The DIY also advocates the entrepreneurial spirit, the community spirit but also an underlying form of rebellion, individualism and mistrust of bureaucracy (Delfanti, 2010). Fab labs can indeed cause some risks. Thus, by facilitating Do It Yourself and Make almost anything (Gershenfeld, 2012), these places could eventually contribute to the uberisation of knowledge (Scaillerez and Tremblay, 2017a). It would then be a negation of skills acquired by some in favor of a pseudo-universal knowledge.

Previously, it was almost unthinkable that individuals could manufacture a multitude of products by themselves because the purchase of technological equipment was expensive, difficult, rare, if not impossible. However, the affordability and availability of scientific equipment has increased significantly in recent years. There are now various ways in which the cost of setting up a community manufacturing workshop becomes more affordable through the purchase of used equipment in particular. The possibility offered by these fab labs to construct or build by yourself such goods (3D printer, DIY tools, mechanics, carpentry objects ...: Devendorf and al., 2016) could then contribute to a loss of levels of technical expertise (advanced technical and craft skills) and real skills of professionals to the benefit of a generalization of amateur creations. Fab labs can then raise some concerns, since it can be dangerous to tinker with technology outside scientific institutions and this can lead to potential risks for people and the environment. One could then fear a deskilling effect of the actors who use these places and their devices, but also risks of injury or health with non-standardized instruments. It may be necessary to frame these new forms of activity emanating from digital, or at least the resulting products.

Fab Labs, a Risk of Deterioration of Work and Health

Practices that are explored in fab labs carry a culture of “doing”, rapid experimentation and sharing, to a degree that depends on the forms considered (Lallement, 2015). Promoting autonomy and collaboration, these practices have also triggered a shift in working relationships. One of the aims is to undo the hierarchical relationships of previous systems to install more horizontal, participatory and open modes of cooperation.

By bringing the Make almost anything into private garages the boundaries between amateurs and experts, between scientists and citizens, between universities and homes are potentially reconfigured. Other limitations become particularly salient and problematic through these changes: between responsible and criminal uses, between safe handling and dangerous experiences, between the garage and the outside world. Indeed, various health devices or dangerous arms could be easily created, and this surely needs to be controlled.

SOLUTIONS AND RECOMMENDATIONS

This new economy, driven by technological advances and the increase in the number of fab labs around the world, could also lead to certain deviances such as increasing, or even creating new occupational risks, or degrading working conditions, by facilitating the penetration of work in all spheres of life of the user of these places. These excesses would go against the primary reasons why fab labs were created. It would be necessary to establish a regulatory framework. For the moment, all the writings on this theme, whether it be the ministerial reports, the jurisprudence, or the texts of law on the international scale, do not really address any of these issues (Scaillerez and Tremblay, 2016 and 2017a).

FUTURE RESEARCH DIRECTIONS

With regard to fab labs, there is a lack of dissemination of information that could partly explain why these places are still very little known and used mainly by certain categories of the population (analysts, programmers, designers ...). However, fab labs could serve everyone (artisans, traders ...) and participate

in the revitalization of several forms of very diverse territories (rural areas, small towns, remote areas), although they are for the moment rather concentrated in large cities (Tremblay & Scaillerez, 2020)

In addition, most writings dealing with the notion of fab labs are essentially composed of studies and field surveys of concrete achievements, but there is little analysis, let alone confrontation with a precise framework of analysis. Above all, there are a large number of descriptive studies written by technology professionals. Research on fab labs is for the moment composed of very technical studies on high technology or hard sciences like biochemistry, but the studies in human sciences and those intended for the popularization of the subject are few.

One can even add that most publications tend to be very favorable to third places, and rather uncritical. On the other hand, the possible limits, risks of deviance, malaise and other dysfunctions that one could meet in this type of place tend to be neglected.

Finally, studies on the relationship between fab labs on the one hand, and innovation and entrepreneurship on the other are emerging, but research on the subject is still in emergence, so for the moment it is impossible to conclude on their results, as well as on significant impact in these two areas.

CONCLUSION

Fab labs could be of greater importance in the coming years, given the proliferation of fab labs around the world. This new craze testifies that these laboratories deserve special attention because they can provide precise answers to certain societal and economic issues. However, the implementation of these new forms of work and collaborative sharing can lead to a number of risks and raises new questions that have not yet found their solutions. If some of the people behind these labs see them as a more democratic mode of access to various technologies, exchanges of knowledge and workplaces, tensions and risks can sometimes appear between users and call into question the associated advantages to their democratization.

KEY TERMS AND DEFINITIONS

Collaboration: Behavior resulting from exchanges, mutual aid and sharing of skills between manufacturers, as well as the provision and sharing of materials (tools and materials) present in the fab lab to create a manufactured object in common by the users of the place.

Exchanges: Sharing of knowledge and experiences between manufacturers in order to develop forms of manufacturing in the best conditions.

Manufacturer-e-s: All persons (experts or amateurs) who use the fab lab and who wish to manufacture a material or immaterial object.

Manufacturing: In a fab lab, manufacturing corresponds to a material object (3D printer ...) or intangible (software ...) developed by the manufacturers present in the place.

Manufacturing Laboratory: A place that welcomes all types of manufacturers by providing all of its tools and materials, while creating a climate conducive to exchanges and collaboration.

Mutualisation: Pooling of all skills, all tools (cutting machine ...) and all materials (wood board, paper ...) in order to encourage collaboration and manufacture between manufacturers.

Skills: All the knowledge, experiences, know-how and mutual expertise held by users of a fab lab in order to create a collective manufacturing.

The Role of Networks in Local Governance

2

Eugenio Salvati <https://orcid.org/0000-0003-2067-8698>*University of Pavia, Italy*

INTRODUCTION

In this historical phase in various European countries, we are assisting to a redefinition of the competencies among different level of governments; this decentralization involves a redistribution of power, authority and monetary resources towards lower level of government implying so new arrangements in the relationship between these different authority structures (Haveri 2006). This process defines a framework characterized by a high dispersion of authority and competencies which are fragmented among these various levels around which the governance issues are organized, determining so that arrangements of power, competencies and relationships that is called multilevel governance (Hooghe and Marks 2003; van Popering-Verkerk and van Buuren 2016).

The devolution of powers, authority and resources which is at the base of the multilevel model, feed the amplification of fragmentation that is a distinctive feature of new governance systems; an unavoidable produced by the need to foster and improve specialization and bring services production/supply as close as possible to citizens (Peters 1998; Hooghe and Marks 2003; van Popering-Verkerk and van Buuren 2016).

As a result of this state of affairs, the great challenge that local governance is facing at the moment is the quest for coordination and cooperation between and within governance levels and among different actors (Peters 1998), otherwise every effort to realize a more efficient and effective governance model could be useless (van Popering-Verkerk and van Buuren 2016).

If we take in consideration, for example, the production of public services at the local level, we can appreciate that inter-municipal co-operation and interaction networks are becoming more relevant (Haveri 2006; Klok et al. 2018; Previtali and Salvati 2018), requesting the effort to foster new organizational models and instruments for coordination.

These networks which can represent different levels of government and/or different actors within the same territory, may be characterized by the simultaneous presence of different interests, power asymmetries, conditions of interdependence and organizational differences. Such a concept defines an organizational innovation that implies for public (local governments, public administration) and private actors (citizens, associations, profit and non-profit organizations) both challenges and opportunities.

The broader aim of the chapter is to identify some of the main features that characterize these networks, which are their goals in the framework of the occurring changes to local governance, trying to sketch which is their role and the opportunities connected to this organizational innovation for public administration and the implications for the connection between p.a. and social actors, as it is well represented by a particular experience of governance network like the one of the inter-municipal cooperation.

BACKGROUND

The Governance Concept: a Useful Tool to Understand Networks' Functioning?

The scientific debate on network cannot be totally disconnected from the one on governance, a field of research that has become extremely popular in the last decades, in particular in its stream of research connected to the New Public Management's approach that, briefly said, was based on the strong assumption of a reduction of the Government and public sector's role in services provision (Klijn and Koppenjan 2000; Klijn 2008; Klijn and Koppenjan 2012).

The most known definition of governance is the one provided by Rhodes (1996) that defines it as a system of self-organizing and inter-organizational networks which has changed the old hierarchical bureaucratic model of power and authority centralization typical of the modern state. The adoption of informal practices and organizational provisions by the private sector is characterizing the new governance model that stresses the role of multiple relationships between public and private actors. Such an organizational perspective allows to understand the changing process in governing and policy making, with new arenas in which policies are defined/implemented and multiple actors within them that can contribute to their definition and implementation (Montin 2000). Relevant is the emphasis posed on processes rather than on structure and on the diffusion and fragmentation of power and authority.

Following the literature review on governance made by Klijn (2008, 507-508) four strands characterize this field of studies:

1. governance as corporate governance which refers to the function of public administration;
2. governance as new public management or market governance, which is focused on the analysis of performances and implementation;
3. governance as multilevel governance pertaining the study of networks across various levels;
4. governance as network governance that focus on the interaction between different organizations within a complex pattern of (multitier) relationships.

Considering the main features of governance like the presence of both informal and formal relationships, involvement of both public and private actors, multiple connections between actors, seems difficult to consider it not strictly related to the network model, which is the direct product of dynamic processes and continuative interactions among actors (Klijn 1996; Klijn and Koppenja 2000; Verveij et al. 2013).

As wisely pointed out by Klijn (2000; Klijn and Koppenjan 2012) it is not necessary to create a distinction between governance and governance networks because the first is an ongoing process that happen within the "boundaries" created by the governance networks. In fact they are both defined as the "public policy making and implementation through a web of relationships between government, business and civil society" (Klijn 2000, 511). What emerges from the connection between the concepts of governance and networks is the fact that networks are a specific arrangement of interdependencies and relationships between actors that allows governance to deploy its self-steering and self-organizing capacity (Klijn and Koppenjan 2012).

Network as a Theoretical Framework

During the last years network has become, like governance, a catch all term implied in a variety of ways and for different purposes, not always in a correct and pertinent mode: a situation that has contributed to feeding confusion and lack of clarity about the role of this concept and its heuristic and analytical potential.

According to scholarly literature we can identify two approaches concerning the explanation of what a policy network is (Börzel 1998): the first one is referred to the “interest intermediation school” and conceives policy network as an arena for interests intermediation, the second one is related to the “governance school” and defines network as a governance arena in which independent organizations co-ordinate themselves, pool their resources and define precise mechanisms in order to define and/or implement policies.

As stated by Börzel the two models are not mutually exclusive and frequently in the empirical reality they can be complementary, due to the fact that policy making is obviously influenced by governance arrangements (Lewis 2011). This connection is underlined also by Sørensen and Torfing (2007) which define governance network as a relatively stable horizontal articulation of interdependent actors which interact by the means of negotiation that take place in self-regulating framework. Furthermore Börzel sketched a minimum definition that conceives a policy network as a “set of relatively stable relationships which are of non-hierarchical and interdependent nature, linking a variety of actors who share common interests regarding a policy and who exchange resources to pursue these shared interests acknowledging that co-operation is the best way to achieve common goals” (1998, 254).

Linking together the character of governance relationships that are informal and non- hierarchical and of policy making as the result of the interaction process between multiple actors, Börzel pointed out two peculiar elements of a network arrangement: the fact that it is a relational concept (it needs at least two actors to take place) and that it is intrinsically dynamic in its nature. This dynamism underlines that the network is first of all a process, determined by actors’ interactions which are steered by interests and power asymmetries (Klijn 1996; Haveri 2006). The stability of these interactions within the network is what defines its structure that is so the product of the cumulative effect of the ongoing relationships between partners (Klijn 1996).

Under this point of view network exists because (Klijn 1996): a) actors pool their resources, b) these actors become so mutually dependent from these resources (and of their sharing modality), c) it defines a model of collaboration and a common management of resources that contribute to institutionalize the network via the constitution of stable patterns of collaboration (i.e. the creation of institutions).

Klijn analysis perfectly shows the central role exerted by resources in defining network existence. Resources and their sharing are essential in order to allow to pursue collective outcomes and to guarantee to reach converging interests (Börzel 1998). Despite the fact that the final goal is improving cooperation, it is possible that the network could be characterized by an unbalanced distribution of these resources, so leading to the creation of power asymmetries. The fact that interdependency is the main character of a network means that the actors need one another, but it does not preclude differences and unbalance. The degree of dependency and the number of relationships can vary according to various elements like the actors’ goals, the willingness to use their resources, the level of mutual trust etc. (Scharpf 1978; Klijn 1996; Börzel 1998; Haveri 2006).

Under this point of view, collaboration between actors within a complex model of networks can be primary conceived in terms of structures and processes which create the environment within which actors can allocate resources in order to reach the defined goals and to better coordinate their activities (Vangen et al. 2015). Consequently the capacity to have a steady and continuous flow of information between

actors, which guarantees a channel of information and avoids huge asymmetry among partners, it is a crucial element to understand how a network is managed and how effective its leadership is – especially in more complex systems - (Vangen et al. 2015; Cristofoli et al. 2017).

The degree according to which this condition of interdependency may vary can be defined as the gap in the strategic power of the actors (Stoppino 2001). The more one (or more) actor has a dominant position in terms of owned resources and willingness to imply them and the more another actor(s) has scarcity of disposable resources and difficulty to fully imply them, the easiest is that the network can move towards a condition of domination and dependency instead of coordination and interdependency.

The type of gap in the strategic power also influences the strategic interactions among the actors and so the output of these games, making the uncertainty a characterizing feature of the functioning of the networks (Klijn 1996; Haveri 2006). Uncertainty will be higher: a) the more complex the tasks and goals of the network are, b) the less institutionalized the pattern of strategic interaction among the actors is.

Properly for the risk to incur in a series of uncertainties, it is necessary for the network to move towards institutionalization in order to reduce the opportunities for defection, free riding and exit, and guarantee conformity and cooperation for all the involved actors.

Networks' Tasks

The main goal of network arrangement is to (try to) reduce complexity and make the interactions among various actors easier (Hovik and Hanssen 2015). This 'umbrella task' gathers different goals that can be achieved through the network's actions: these goals can be all simultaneously pursued and achieved or they can only be partially reached, what is characterizing is that all of them can be pursued only by cooperation.

Governance network is so the result of the various strategic interactions between partners and of the agreement among them in order to define rules, common settings, tasks and instruments useful to assure a shared enjoyment of the pooled resources (Klijn 1998). There is a bidirectional relationship between network and organizations because they mutually influence one another. As stated before, the interactions between membership organizations – cooperation, conflict, strategies - define the borders of the network, and the network provides an arena with ties and opportunities within which the actors cooperate and strategically act (Thelen and Steinmo 1992). This is the connection that we can find between structure and agency in the terms carried on by, for example, the historical institutionalist approach. According to this stream of research actors are strategic in the sense that they want to realize certain goals or gain certain rewards and they do so in context – the institutions - that make the use of certain strategies compared to others more effective (Hay and Wincott 1998).

Following this premise, the first task is the creation of stable patterns of action between the members of the network in order to pursue the reduction of uncertainty and transaction costs as much as possible (Borzel 1998; Turrini et al. 2010). This can be reached by the definition of a common framework of stabilized rules, behaviours, procedures etc. as the institutionalized product of the strategic interactions among partners (Klijn 1996). These interactions gather not only the interests of the single actors but also the connections defined by mutual trust, the formal/informal communication and the sharing of resources. All these elements are useful to enforce the institutionalized rules and make more predictable individual behaviours.

The second task is the effort to reduce the level of fragmentation by stimulating coordination among actors (Kazepov and Barberis 2013; Hovik and Hanssen 2015). Coordination does not necessarily imply

a homogenization of interests and goals but is more related to the need to reach a new way to organize the governance structure and to plan and supply services.

The third element is the ability to produce collective outcomes which are both the product of a conciliation of different interests and the capacity to achieve better results by improving policy's effectiveness (Börzel 1998). The institutionalization of networks allows to solve cooperation dilemmas and guarantee the conformity of actors to collective decisions.

A final element concerns the stabilization of a constant flow of resources and the definition of common rules (Turrini et al. 2010). For the survival of a network it is fundamental to guarantee a stable exchange of resources among the involved actors (Klijn 1996); an exchange that determines the degree of interdependence within the network. Furthermore it needs rules which are generalizable procedures that provide actors with ties and opportunities within the network. Formal and informal rules are the elements that stabilize conformity, regulate the interactions among actors and assure a proficient cooperation to actors because they provide stability to the environment in which network members operate.

Beside rules and stabilized patterns of cooperation, it is fundamental the role of the leadership and network management to guarantee coordination, even despite differences in interests and difficulties in cooperation (Cristofoli et al. 2017). It is the leadership that can decisively contribute to create new models of cooperation within a governance network, in particular by fostering trust among the partners and stimulating cooperation (Ansell and Gash 2012; Hartley et al. 2013) due to the relevant impact that managerial strategies have on trust and its enforcement (Klijn et al. 2010) and on uncertainty reduction.

Leadership/management has the duty to steer the network dynamism and to guide the process of cooperation by supporting the policy making process, activating resources and reorienting networks' tasks according to the different needs and the mutate external conditions (Turrini et al. 2010).

The Transformation of Local Governance: Between Fragmentation and Coordination

One of the main aspects concerning the transformation that is occurring to local governance and to public services production (especially in sensitive sectors like social and healthcare policies) is the enforcing process of territorialisation which has as its main feature the task to bring public services as close as possible to citizens, enforcing the effectiveness and the personalization of the services, but also transparency and participation for citizens and associations (Bifulco and Centemeri 2008; Andreotti et al. 2012; Previtali and Salvati 2017).

Local governance is a phenomenon that is undergoing several and continues paths of change that necessary pertain to the relationship that occur with society and territorial actors; an extremely relevant issue if we consider that (local) governance implies also the joint self-steering capacity of a given territory (Peters 1998; Bouckaert et al. 2002).

Undoubtedly transformation in local governance is the product of the changes occurring to contemporary societies (Bouckaert et al. 2002) but it is also the result both of the changes occurring to the local government model and of the competencies attributed to local actors (public and private) (Rhodes 1997; Peters 1998). As pinpointed by Haveri (2006, 33) local governance is a concept which defines 'the many changes that can be seen in the way municipalities and other local-level actors solve problems and respond to societal challenges at local level'. What is more important – at least for the purpose of our focus - is the fact that at the core of the new model of governance relies the need for actors to seek, feed and guarantee new strict and effective instruments of cooperation which by pass the traditional hierarchal organization of authority (Haveri 2006; Verweij et al. 2013).

Under this point of view the public actor is becoming more and more involved in building cooperation and partnerships with social actors, Third Sector and other local authorities in order to produce new services, employing a course of action that can be defined as the effort to build governance networks (Haveri 2006; McGuire and Agranoff 2011; Previtali and Salvati 2018).

This model perfectly resembles what, generally speaking, means Rhodes when he wrote about governance (1996), in particular because this concept allows us to understand how services production and delivery is now characterized by the active presence of the private and voluntary sectors (1996, 658) and by new inter-organizational linkages which, as outlined by the network theory, stimulate the opportunity to build new organizational instruments for coordination and resources' management.

This framework is characterized by a high dispersion of authority which is fragmented among different actors involved in decision making and in policy implementation (van Popering-Verkerk and van Buuren 2016; Previtali and Salvati 2018), and various levels around which the governance issues are organized and managed (Hooghe and Marks 2003; van Popering-Verkerk and van Buuren 2016). For these reasons the structure of local governance is gradually moving towards a major coordination among actors, creating governance arenas based on mutual trust, cooperation and pooling of resources, as explained by the network theoretical framework.

Over the last years different realms of service production have steadily shifted towards this organizational model. For this reason the network concept is useful to capture the shift occurred in local governance organization in the last decades: a movement from the classical bureaucratic and hierarchical structure of authority to a more informal net of actors – public and private – which at different level participate to policy formation and implementation (Lecy et al. 2014), and that encompasses both formal and informal rules and procedure (Klijn 1996; McGuire and Agranoff 2011; Lecy et al. 2014; Hovik and Hanssen 2015). The governance model produced by these arrangements is based on a complex system of multiple interactions between different actors – municipalities, public agencies, associations, Third Sector etc. – which are not able to reach their policy/interest goals alone. Aware of this limit, they improve coordination by the means of several interdependency nodes with the general task to realize common and shared goals. This improvement of coordination created by this arrangement is contributing to strengthen effectiveness in the throughput and the output phase (Schmidt 2013), which means to enforce both the processual and the implementation phases of decision making.

As stated before, in order to be effective, these networks are necessarily based on common and shared rules that guarantee the cooperation and the conformity of all the actors, reducing the risk of defection and/or exit. All these features make the network an institutionalized framework for co-ordination among multiple actors, in particular for what concerns the sharing of resources and interests (Börzel 1998): network partners are mutually dependent for the planning and realization of policies/actions and for producing and delivering services. As enlightened by Rhodes (1996, 658), “these networks are made up of organizations which need to exchange resources (for example, money, information, expertise) to achieve their objectives, to maximize their influence over outcomes, and to avoid becoming dependent on other players in the game”.

How these arenas are composed, influences the level of complexity within a certain network: the complexity tends to rise according to the level of interdependence among the actors, and the differences between them can be the product of different ideas about collective problems and/or solutions to these problems and also to the type of connections that link actors (Verweij et al. 2013; Hovik and Hanssen 2015). Following these premises, the best way to determine how the network is organized imply to know if the network: a) arranges horizontal instruments of coordination to improve cooperation (Scharpf 1978; Verweij et al. 2013), b) tries to imply some forms of centralized control (McGuire 2006), c) involves a

multilevel structure (which is not in contradiction with a horizontal logic of functioning) (Hooghe and Marks 2003).

Considering these issues at stake, we can affirm that network management is focused on the institutional and organizational arrangements implied to facilitate interactions, produce shared decisions and manage different interests and point of views from the various actors. These organizational instruments are more and more needed because a network model of governance requires an open approach towards the involvement of new stakeholders within the governance arena (Verweij et al. 2013), according to a horizontal model of cooperation in which it is difficult to detect a hierarchy between organizations.

The degree of openness within a governance network, especially at a territorial level, may vary according to two elements (Provan and Lemaire 2012): the first is the need not to open up the network with a mere logic of selective integration, that means the involvement of all those organizations which are linked together simply by broad interests (geographic, sectorial, political etc.), the second is the major or minor necessity to build strong or soft ties among the network members (i.e. if you need to provide some essential services, it is probable that you need to have strong ties in order to improve homogeneity and efficiency). Both these elements can be related to the governance structure which, according to its minor or major openness, can impinge on features like authority, influence, power, effectiveness, accountability and so on (Vangen et al. 2015).

One point worthily to underline is: the more the governance structure is open to different actors which can “come and go” according to their interests about the agenda, the more complex it will be to construct efficient instruments of coordination and to detect responsibility and keep the various actors accountable (Vangen et al. 2015). Conversely, for new actors entering in an established network it can be costly in the short-medium period because it implies an investment in terms of learning (about rules, norms, behaviour etc.) and relationships to be established (Klijn 1996).

These issues are at the core of the transformation now occurring to local governance: providing a solution for these organizational problems giving territorial actors the opportunity to effectively act in a coordinate way and so improving their effectiveness in services provision. This is the way the network model is becoming a prominent feature in local governance arrangements.

SOLUTIONS

It is easily understandable that governance networks fulfil numerous tasks of extremely relevant nature. One of the most prominent example of organization via networks is represented by inter-municipal cooperation which represents a rather important example of network coordination at local governance level. These arrangements are thought to tackle with inefficiency, allocation difficulties, problems in designing and implementing policies and fragmentation in resources, knowledge and services connected with conditions of elevated municipal fragmentation, in particular in situations characterized by a high number of small municipalities.

In such a framework the institutionalization of cooperation involves for municipalities some transaction costs like the necessity to monitoring the evolution of the agreement. Nonetheless it guarantees important outputs like the enhancement of municipal ability to produce and deliver services and so solve problems of effectiveness (Klok et al. 2018). The more these cooperation agreements are the result of a voluntary self-organization in creating a new system of inter-municipal collaboration and not an imposition from a higher level of government, the more it seems to be a valuable way to provide a valuable solution for fragmentation (Kwon and Feiock 2010).

For municipalities the creation of a governance network can be the collective answer to numerous individual problems, in particular thanks to a new scale level which allows to plan and implement innovative services in a more efficient way. Furthermore when we talk about inter-municipal cooperation we refer not only to the creation of an agreement between public actors but also to the direct involvement of private actors (profit and non-profit organizations, Third Sector etc.) which thanks to this new structure have the opportunity to directly cooperate with municipalities both in the planning and implementation phase of local policies (Bifulco and Centemeri 2008; Previtali and Salvati 2018).

The analytical framework provided by the network governance approach, allows us to understand the more recent deployment of public-public and public-private relationships in the context of local governance; a context in which there is not a simple externalization of competencies and duties to the private sector with the public actor relegated to a regulative function, but a permeation (a sort of fusion) between the two actors in order to better pool resources, produce a more efficient knowledge of the social context in which the network operates and plans more effective policies and actions.

Under this point of view the network governance arrangement provides an extremely interesting and valuable solution to collective action problems and services' provision. Network creates an environment in which different actors can share resources and produce policy decisions based on the mutual trust that is guaranteed by the formal and informal rules defined by the network. Furthermore it provides a new arena in which to plan and implement policies with the aim to supply new and more effective services: this is particularly important in fragmented contexts like in the local governance arena – a condition that mainly pertains to the administrative organization based on several municipalities - in which we have a proliferation of actors and a dispersion of resources.

In a framework defined by municipal fragmentation and dispersion of resources and knowledge, the high level of adaptive capacity proper of the network makes it a valuable instrument in order to reach collective goals, thanks to a deeper and better involvement of actors (Verveij et al. 2013).

Furthermore the network provides an extra competence for organizations to “stretch and leverage limited resources, enhanced learning, which leads to greater innovation and better service quality; (...) the ability to achieve economies of scale (...), the capacity to be far more flexible than a tradition bureaucracy” (Provan and Lemaire 2012).

Network seems to be a valid analytical framework by which to explain how different actors try to resolve both problems of fragmentation and goal seeking by institutionalizing a new model of governance based on the strengthening of the coordination phase. Coordination is the core topic in order to overcome the many problems produced by the inter and intra institutional fragmentation (Barberis and Kazepov 2013), in particular by providing arenas in which it is possible to produce cooperation mechanisms which have been severely undermined in the field of policy making during the last decades. The reconstruction of these mechanisms can allow to realize collective gains, improve effectiveness in policy making and also maximize utilities of the partners involved in the network.

The effectiveness can be measured by the network capacity to achieve the planned goals and provide solutions to collective problems (McGuire and Agranoff 2011). Certainly this is not a proficient way to measure network capabilities and potentials because there is, for example, the occasion that a valuable and good network pursues weak and poor tasks, so we formally have a good effectiveness but an under efficient use of network potential.

The main risk in which this process of change may incur is connected to the governance of the governance issue (Kazepov and Barberis 2013), a condition that in a context of multi-level governance “*can create perverse stakeholder engagement by creating rent-seeking practices*” (Milio 2014), and that can damage innovative forms of governance. In this situation, as stated by Previtali and Salvati (2018), gov-

ernance network could become an element of complexity, or even a crucial problem, more than a good premise for the functioning of cooperation. In our case we can say that the planning and policymaking process may be a victim of a joint – decision traps in which efficiency and innovation are subordinated to veto powers expressed by a different level/actors of governance (Scharpf 1988), in particular in a model in which horizontal co-ordination can create perverse mechanism by which is not possible to solve decisional issues (Börzel 1998), in particular in the absence of a leadership's role with a network.

A valuable solution for the “governance of the governance” problem is a specific and consolidated path of readjustment for local institutions, administrations and societal actors, of their goals, their organizational model defining a real process of institutional adaptation in order to better cope with the new social needs. This path can work only through institutional adaptability, that means the opportunity to combine the organizational continuity with the flexibility required to integrate and interpret the new inputs/demands/needs that come from the society and from the network partners (Previtali and Salvati 2018), finding an equilibrium between bargaining and decisions, between process and structure.

FUTURE RESEARCH DIRECTION

The article has attempted to show the evaluability of the network governance concept as an analytical tool useful to understand the changing patterns in local governance. A tool that seems extremely useful in order to observe and analyse the relevant topic of service provision at local level. Citizens' needs and social answers are changing and becoming more and more complex and for this reason it is necessary to have a new model of policy design which can boost coordination and reduce fragmentation.

Properly for what concerns these two aspects – fragmentation and coordination - the literature on network governance is inquiring the emerging trends that are characterizing the new historical phase of local government and governance. What is important to stress is that in no way a network can be conceived as an instrument to replace local government or government agencies but, as network literature underlines, this peculiar organizational arrangement can have positive effects on policy effectiveness determining a new role for public actors as positive leading partners (Skelcher 2004; Turrini et al. 2010; McGuire and Agranoff 2011; Previtali and Salvati 2018). A new role that can overcome the marginalization of the public sector theorized by New Public Management and repair the negative externalities produced by its hegemonic approach (Klijn and Koppenjan 2012).

Under this point of view we have numerous examples of successful network organizations that helped improving coordination among actors and the effectiveness of their action. Among many we can quote: the Italian experience of the Piani di Zona as inter-municipal arenas with the task to jointly plan and deliver services in the social field (Bifulco and Centemeri 2008; Previtali and Salvati 2018); the inter-municipal cooperation among Aragon small town municipalities for what concerns the delivery costs of urban solid waste services (Bel and Mur 2009); the case of multilevel network coordination for the management of the climate change effects in Norway (Hanssen et al. 2013).

The merging trend that probably should be studied with more attention is properly the role of government (at every level) and public actors within the network. How is it evolving and changing? Is it still moving towards a role of facilitator and co-operating partner? Is there a new centrality of public actor after the era of the New Public Management?

So, what is central and fundamental in every study – both theoretical and empirical – concerning networks is the inquiry of the model of intergovernmental and inter-organizational collaboration (also in a multilevel facet). One of the main research question should be how different networks build models

of coordination in the presence of scarce network own authority (ie no possibility of imposition from a central actor) and power asymmetries. Or even a reflection about the presence of possible hybrid governance structure composed by different arrangements (Klijn and Koppenjan 2012). From a certain point of view this stream can be reconnected and partially encompassed to one of the research clusters about network identified by Leczy et al. (2014) concerning the governance, which is sided by the ones about policy formation and policy implementation. Keeping in consideration that our focus is mainly on governance structures, it is unavoidable that it intersects both with policy formation and implementation, two phases that are influenced by the way in which the network is conceived.

Furthermore it could also be extremely interesting to reflect about the relationship that occurs between network organizational arrangements and outcomes/performance effectiveness (Klijn et al. 2010; Turrini et al. 2010). Which structural (rules, resources distribution, trust etc.) and/or processual elements (relationships, policy implementation etc.) contribute to the success/failure of a network? Is it, for example, possible to connect level of trust and leadership/management styles with network type of outputs?

From a methodological point of view is worthy as stated by Lewis (2011) to combine different approaches (from organizational studies to political science, sociology, anthropology, economics etc.) and methods (both qualitative and quantitative) in order to better capture a phenomenon that is in continuous evolution.

In a nutshell we can say that the research on network still has a great space for inquiry and this is probably connected to its dynamic nature and the fact that it is an arena open to different type of contributions but that can easily be fostered according to the various context and to the different needs expressed by the involved actors.

CONCLUSION

We have seen that the network concept is useful to analyse and understand for which reason and by which organizational arrangements, independent organizations (both public and private) decided to pool in common their own resources, coordinate their actions and institutionalize their cooperation by the creation of linkages, rules and routinized behaviour (Klijn 1996, 2008; Börzel 1998; Klijn and Koppenjan 2000).

For this reason networks can be considered as an organizational form of governance useful to respond to societal specialization, fragmentation and differentiation: a state of affairs that in the complexity of modern times can lead to grid lock in the absence of effective coordination mechanisms. Functional and territorial differentiation, the fragmentation of competencies and authority/resources, the growth in the number of relevant actors which take part to the decision making process, are all issues that contribute to create subsystem of sectorial specialization with limited competencies which limited the problem solving capacity. The unavoidable output is the interdependence of actors and resources and the need to create coordination mechanism in order to solve collective problems. The need of coordination, mobilization of social resources and a more effective model of decision and implementation has led to the enforcement of networks.

Networks allow to pool and mobilize dispersed social resources, through coordination they guarantee the conformity and cooperation of involved partners and enforce the relationship between public and private actors with a non-hierarchical and interdependent model of governance (that can be both horizontal and/or multilevel).

So networking can be interpreted as a solution for a collective action to problems in a peculiar context like the local governance, where in presence of extreme level of municipalities fragmentation, disper-

sion of resources and multiplicity of actors represent a striking issue when we look at, for example, to cogent social policies like the fight against poverty, social exclusion and social housing (Barberis and Kazepov 2013). Policy issues in which the size of municipalities, their ability to reconnect actors and mobilize resources are all strategic themes in order to effectively plan and supply services. This problem enlightens the urgent need to provide new institutional instruments of governance, that allow those actors to act in a more effective way, overcoming the institutional deficiency produced by a fragmentation, that in a certain context can be defined as pathological.

KEY TERMS AND DEFINITIONS

Coordination: The activity to organize according to a task, a role and/or a duty different actors/organizations involved in a cooperative action.

Fragmentation: The division of actors/resources/knowledge and services in different streams that make complicated the cooperative action.

Institutionalization: The creation of stable patterns of action and behaviour, based on routinized formal and informal rules.

Network: A model of cooperation between different actors based on the pooling of resources and the definition of common tasks.

Power Asymmetry: The unbalance of resources and authority among the actors which operate in the same network.

Process: The sum of dynamic interactions that occur among actors.

Structure: The stable framework within which actors operate. It defines ties and opportunities for agents' actions.

Territorialisation: The shift of resources, authority, and competences towards the lowest levels of government.

The Relationship Between Performance Measures and Overall Performance in the Manufacturing Environment

Raman Kumar

Chandigarh University, India

Harwinder Singh

Guru Nanak Dev Engineering College, India

INTRODUCTION

Globalization and liberalization of today's markets economy have posed new challenges to all manufacturing organizations to examine and improve their capabilities. Performance measurement systems are expressed as the overall set of factor used to quantify both the efficiency and accomplishment of the act. Performance evaluation and enhancement is a challenge for small scale manufacturing organizations in the competitive globalized world. Performance measurement represents the effectiveness and progress of activities involved in a manufacturing system. Performance measurement ameliorates the flow of information which avails in enhancing market position of the organization and may likewise fetch new customer (Li et al., 2006). Performance measurement helps in identifying both frail and solid key territory of the system and transmute should be possible in like manner. The overall performance of a manufacturing organization can be enhanced by thoroughly examine and monitor the activities of all departments such as production, inventory, maintenance, etc. involved in the manufacturing system (Gomes et al., 2006). The block diagram of manufacturing system is shown in Figure 1.

Important Performance Measures in Manufacturing System

The output of manufacturing system can be characterized by the final product, reputation and profit etc. The activities involved in the manufacturing system should have an influence on output and performance of the system. Researchers have explored the various factors influencing the performance measure of manufacturing system. The performance measures of manufacturing system are linked to the overall performance of the system. The flow chart of present work is shown in Figure 2. In the present work, only four performance measures are selected by brainstorming and expert's opinion while keeping in view the setup of small scale agricultural equipment manufacturing organizations.

Delivery Performance

Delivery performance is characterized as a height up to which customer demands are fulfilled by the organization within the expected time period. The continuous change in the operational environment, inventory level of raw material must be taken into account and the functional areas such as marketing and operation are having a significant effect on time delivery performance (Nakandala et al., 2013; Marques

DOI: 10.4018/978-1-7998-3473-1.ch027

Figure 1.

Figure 2.

et al., 2014). The delivery performance helps in diminishing the organizational costs and improves the customer satisfaction levels. The higher uncertainty in delivery time raises the inventory level and makes distinctive consequences on the working performance of the organization (Chen et al., 2006).

Operational Performance

A questionnaire based study of SMEs ensures the impact of innovation capabilities on operational performance (Minna, 2014). A strategy has been proposed to gauge and enhance the operational performance of an organization (Padavano, 2004). The involvement of supplier and customer are critical for upgrading the operating performance of manufacturing organization (Feng et al., 2013). The questionnaire study of Taiwan's manufacturers revealed that the certification of ISO 4001 help in achieving excellence in operational performance (Chung et al., 2005).

Employee's Performance

The effective training of workers improves the skill proficiency as well as employee's performance. The up gradation of employee talent helps in propelling productivity and enhances overall performance of the organization (Jehanzeb and Bashir, 2013). The lack of ability and lack of motivation are two key inhibitors in employee performance and exert ought to be made as needs be to enhance. The employee's performance can exceed expectation by developing creative and supportive working environment (Lee, 2006; Newman et al., 2011).

Customer Relationship Performance

It has been evident that fetching of the customer through a decent service quality help in keeping up the competitive position in the market (Izquierdo et al., 2005). Human resource management has a significant impact on customer satisfaction and organizational performance (Gómez-Cedeño 2015). The customer loyalty can be improved by customer satisfaction and decidedly identified to benefit (Helgesen 2006). It has been shown that there is a direct relationship between customer satisfaction and organizational performance (Wiele et al., 2002). It has been stated that market turbulence has a negative effect on the relationship between CRM practices and organizational performance (Mohamad et al., 2014). According to Zigan and Zeglat (2010), customer satisfaction and faithfulness are critical parameters for measuring non-financial performance of an organization.

The environment of manufacturing organizations is characterized by unpredictable market change due to the customer response. In the competitive globalization era, the manufacturing environment becomes turbulent and uncertain to meet the market expectation. Although, existing works show the relationships between parameters and output/performance of manufacturing system using statistical analysis. Researchers have successfully shown the relationship between success factors/parameters and different performance measures in various sectors such as banking, service, trading etc. However, the relationship between different performance measure and overall performance of manufacturing system has stayed unfamiliar. Therefore, an attempt has been made to explore the relationship between different kind of performance and overall performance of manufacturing system. An attempt has been made to explore the different performance dimensions of manufacturing system. The next chapter presents the extensive relevant review of reputed journal research papers and scientific information available in database.

LITERATURE REVIEW

A little work has been accounted for to demonstrate the linkage between different performance measure and overall performance. Gomes et al., (2006) explored the dimension related to organizational performance of manufacturing industry. The result showed that high performance manufacturing organizations are emphasis on performance aspects related to employees, customers and market share. Berrah et al., (2016) introduced an improvement contribution concept in the field of performance measurement. The presented framework helps in the decision making process in order to improve overall performance of manufacturing system. Elinger et al., (2000) examined the effect of interdepartmental integration in order to achieve better service quality. The result showed that effective relationship between marketing and logistics department improves the delivery performance of the organization. Gomes et al., (2004) concentrated on both financial and non financial measures in the context of performance measurement. It has been inferred that weight age of non financial measure should be more on the assessments of manufacturing performance. Valsamakis and Sprague (2001) presented the role of customer relationship in the performance of small and medium manufacturing organization. Quesada et al., (2012) examined the relationship between success parameters and performance of supply chain management. A survey based research on US pallet industry was performed to validate the proposed framework. Gunasekaran et al., (2004) and Rao et al., (2011) stated that delivery performance is a key metric in supply chain per-

Table 1.Relevant Literature Review

S. No	Author(s)	Year	Descriptions
1	Rezaei and Ortt	2018	· Explored the relationship between functional performance and overall performance. · SEM was used to test the hypotheses. · R& D and Production performance has positive relationship with overall performance.
2	Buli	2017	· Performed a survey research work consist of opinions of 171 SME managers. · Applied multiple and linear multiple regression were applied to test the hypotheses. · Integration of entrepreneurial and market orientations directly linked with performance improvement of small business.
3	Chen and Wu	2016	· Investigated the relationship between customer relationship management (CRM) and business performance. · CRM is directly effect on financial and non-financial performance in supply chain management.

formance measure and effective delivery performance help in achieving excellence in business. Minna, (2014) performed survey based research to explore the relationship between innovation capability and performance. The results showed that innovation capability has more impact on financial performance than operational performance. Coltman et al., (2011) examined the relationship between customer relation management (CRM) and firm performance. The result showed the direct relationship between CRM and performance. Pereira and Osburn (2007) made an attempt to find the impact of quality circle on employee attitude and performance. The finding revealed that quality management has more impact on job performance which results in improving the productivity of organization. The rest of relevant literature is presented in Table 1. The next chapter deals with the design of the study, which includes development of research model and formulated hypotheses.

MAIN FOCUS OF ARTICLE

Literature revealed that researchers have made successful efforts to examine the relationship between different performance measures and success factors. In this work, an attempt has been made to examine the relationship between four important performance measures (viz. operational performance, delivery performance, employee's performance, and customer relationship performance) and overall performance. The efforts of small scale agricultural equipment manufacturing organizations are mainly focusing on core activities i.e. production of products. The small agricultural firms has mainly the 5-7 shops viz. Welding shop, Sheet metal, Machining, Painting, assembly, inspection, where the workers have to perform tasks. Only few firms are using or recently purchased automatic machines in the sheet metal shop and desire to impart training to the workers on these machines during manufacturing weak days. The small scale

Figure 3.

agricultural equipment manufacturing organizations are involved in manufacturing of low or medium duty equipments such as cultivator, disc harrow, grass and stub cutter, etc. The overall performance of manufacturing is characterized by quality of the final product, financial output, reputation in the market etc. A path model consists of 12 observed variables, and four performance measures (latent variables) was developed and tested using SPSS software package and AMOS 21. The delivery performance (DPP) is linked with three observed variables viz. delivery correctness (DCR), delivery completeness (DCM), delivery precision (DP); the operational performance (OP) is linked with three observed variables viz. technological capabilities (TC), process efficiency (PE), flexibility (FL); employee's performance (EP) is linked with three observed variables viz. employee skill (ES), competitive strategy of worker (CS), ability to work in teamwork (TW) and customer relationship performance (CRP) is linked with three observed variables viz. marketing strategy (MS), service after sale (SS), customer satisfaction (CSS). The research path model is shown in Figure 3. The SPSS software package and AMOS 21 was used to measure reliability and confirmatory factor analysis (CFA) respectively.

Hypotheses Development

Hypothesis H_1 : Operational performance has a direct relationship with overall performance

Hypothesis H_2 : Employee performance has a direct relationship with overall performance

Hypothesis H_3 : Delivery performance has a direct relationship with overall performance

Hypothesis H_4 : Customer relationship performance has a direct relationship with overall performance

In next section, the research methodology is presented which includes data collection; data analysis and hypotheses of present work are tested.

DATA ANALYSIS

The objective of present methodology is to explore the relationship between four performance measure and overall performance measures. The four performance measures (viz. operational performance, delivery performance, employee's performance, and customer relationship performance) considered as latent variables. Data was collected through well designed questionnaire as shown in Appendix I. The questionnaire was thoroughly checked by professional before let it out individuals who are occupied with agriculture tool manufacturing firms situated in the northern region of India industrial. The most prevalent, likert scale (five-point) was used to get the importance of sub parameters on the overall performance of manufacturing organizations. . The outcome of the present work is reflected by the respondent of 105 valid questionnaires who are occupied with agriculture tool manufacturing firms situated in the northern region of India. The SPSS software package and AMOS 21 was used to measure reliability and confirmatory factor analysis (CFA) respectively.

Validation of Path Model

During survey based research, researchers should rely more on the AVE and composite reliability than cronbach alpha. Firstly, the research path model was judged for construct validity by examine the convergent and discriminant validity. The convergent validity was assessed by Composite Reliability (CR)

and Average Variance Extracted (AVE). Hair et al., (2010) suggested the acceptable range of composite reliability (CR) > 0.7 for reliability and average variance extracted (AVE) > 0.5 for convergent validity. The discriminant validity was assessed by comparing AVE and squared correlation between two constructs. The threshold value for discriminant validity is AVE > maximum shared variance (MSV); AVE > Average Shared Variance (ASV) and square root of AVE must be greater than bivariate correlation with the other constructs. The values of AVE, ASV, CR and MSV are shown in Table 2. The results of discriminant validity showed that square root of AVE are greater than bivariate correlation.

Table 2. Convergent and discriminant validity

	CR	AVE	MSV	ASV	CRP	EP	DPP	OP
CRP	0.783	0.549	0.167	0.109	0.741			
EP	0.864	0.685	0.211	0.109	0.324	0.828		
DPP	0.921	0.795	0.085	0.049	0.231	0.101	0.892	
OP	0.770	0.533	0.211	0.154	0.409	0.459	0.291	0.730

Goodness Of Fit For First Order Constructs

Lee et al., (2010) suggested the acceptance range of statics variables such as relative chi-square {chi-square value (CMIN) / degree of freedom (df)} < 2, comparative fit index (CFI) > 0.90; root mean square error of approximation (RMSEA) £ 0.10 and root mean residual (RMR) < 0.05. It was suggested to follow above mentioned range for an acceptable fit statics model. The values of CMIN, df, CFI, RMR and RMSEA have been calculated for first order CFA model. The results showed that values of goodness of fit for first order constructs are falling in the acceptable range as presented in Table 3.

Table 3. Goodness of fit

	Chi-square	Degrees of freedom	CMIN/DF	CFI	RMR	RMSEA
First order CFA	59.038	48	1.230	0.982	0.049	0.047
Second order CFA	60.688	50	1.214	0.982	0.054	0.045

Confirmatory Factor Analysis For Second Order Constructs

Step 1 Goodness of fit for second order construct

The values of CMIN, df, CFI, RMR and RMSEA have been calculated for second order CFA models and result showed that all values are falling in the acceptable range as shown in Table 3.

Step 2 Testing of Hypotheses

The second order CFA models have been analyzed to test all the hypotheses developed in present study. The results of second order CFA model 1 showed that all hypotheses viz. H_1 , H_2 , H_3 , H_4 are supported

Figure 4.

Table 4. Results of Second order CFA model

Performance measure	Regression Weights	Standardized Regression Weights	SE	CR	p-Value
OP	1.000	0.813			
DPP	0.659	0.330	0.286	2.304	0.021*
EP	1.169	0.553	0.391	2.921	0.003**
CRP	0.574	0.542	0.202	2.850	0.004**

Notes: * Indicates significance at the $p < 0.05$ level; * * Indicates significance at the $p < 0.01$ level; * * * Indicates significance at the $p < 0.001$ level

in present work. The values of path coefficient are summarized in Table 4 and path diagram results of second order CFA models are shown in Figure 4.

The result of second order confirmatory showed that each of the four performance measure (viz. operational performance, delivery performance, employee's performance, and customer relationship performance) are significantly related to overall performance. The result showed that overall performance explains about 66% of the variance in operational performance, 31% of the variance in employee's performance, 29% of the variance in customer relationship performance and 11% of the variance in delivery performance as shown in Figure 4. The operational performance has 0.813, employee's performance has 0.553, customer relationship performance has 0.542 and delivery performance has 0.330 value of path coefficient with respect to overall performance. The employee's performance and customer relationship performance are found statistically significant with p value < 0.01 and delivery performance is found statistically significant with p value < 0.05 . The last section concludes the research work as well as recommendations for further research.

CONCLUSION

The present study highlights the relationships between different performance measure and overall performance from the perspective of the agricultural tool manufacturing industry. The outcome of first order confirmatory factor analysis attested the significance of observed parameters in respective performance measure. The competitive strategy of worker, delivery completeness, service after sale and flexibility has higher path coefficient in their respective latent construct. This finding apprised that manager should give more accentuation on parameters which are having higher path coefficient in order to improve the performance of organization. The results of second order confirmatory factor analysis ascertain the significance of considered four performance measure (viz. operational, delivery, employee and customer relationship). The paramount finding of the present work is that operational performance and delivery performance has higher path coefficient and lower path coefficient respectively. The present work presented eminent findings for managers as presented standard regression weight of each performance measure with respect to overall performance.

LIMITATIONS AND DIRECTIONS FOR FUTURE WORK

The outcome of present study depends on the sample of the respondent which is limited to manufacturing firm; it is worth testing the validity of the research models in other business sectors such as service and process industries etc. The effect of government policies and cultural issues is not being considered in this research work and can be another issue in future research work. The modified research path model showing mediating relationship between success factors and multiple outputs can be explored in future. There is major future scope in relation to elaborate each performance measure and respective parameters exhaustively.

ACKNOWLEDGMENT

The author's thanks the editors and reviewers for their insightful comments to improve the quality of work. Also, we would like to thank all respondents to our survey.

KEY TERMS AND DEFINITIONS

Average Variance Extracted: Measure of the amount of variance that is captured by a construct in relation to the amount of variance due to measurement error.

Competitive Strategy: Makes an entity better than opponents in order to achieve the goal.

Composite Reliability: Measures the overall reliability of a set of items loaded on a latent construct.

Customer Satisfaction: Quantify the degree to which a customer is satisfied with a product, service.

Delivery Completeness: Number of order deliver completely, that is, without any part delivery.

Delivery Correctness: Complete number of order delivery to the customer without any error.

Delivery Precision: Order reach to the customer at agreed time, that is, without any delay order.

Employee Skill: Ability and capacity acquired by an individual for doing job functions.

Flexibility: Capacity to adjust to changing conditions and necessities.

Marketing Strategy: Moving toward individuals and transforming them into clients for a business.

Process Efficiency: Value of outputs divided by the value of inputs for a business process.

Service After Sale: Arrangement of administration and support after deal.

Teamwork: Workers join their individual abilities in pursuit of a goal.

Technological Capabilities: Capacity to apply information into items and procedure to work and to create technology.

A Model for Success in Agribusiness in the Portuguese Context

2

Carla Sofia Vicente Negrão

University of Coimbra, Portugal

INTRODUCTION

Over time, agricultural enterprises face a number of challenges in order to succeed. In the context of the area under investigation, Boehlje, Akridge, and Kalaitzandonakes (2002, p. 31) refer that:

“Successful agribusinesses will face eight key challenges in the agriculture of the future: globalization, adding value, achieving profitability, defining organizational capabilities, adapting to change, dealing with technological innovation, securing competence and intellectual capital, and achieving organizational transformation.”

In an increasingly digital environment that results in the technological advance of the fourth industrial revolution, referred as Industry 4.0, it becomes interesting to understand the agribusiness success in the Portuguese context, whether enterprises use e-business¹ or not, because all over the world business and government are preparing for this transformation.

The present research may be relevant in a country such as Portugal, because this country has been experiencing a serious economic crisis and to understand the success could be necessary for the agricultural sector to be competitive in an economy digital and boost economic growth. Another reason is that there has been a growth in agricultural production in Portugal in recent years, due to incentives through project funding and government support for the unemployed and young people. However, the lack of competitiveness becomes a problem of the agribusiness sector of Portugal. In this context, it is important to discover and analyze factors with impact on the agricultural business success, so that managers have more information available that can be useful for the definition of future strategies, in order to be more successful.

Given the importance of agribusiness success in a digital economy, the aim of this chapter is to develop a theoretical framework for agribusiness success in Industry 4.0, centered on a holistic approach. The researcher prepares a review of relevant literature on the subject, based on the knowledge of multiple disciplines that contribute to understanding the agribusiness success. The literature review reveals a wide range of research on growth, productivity or performance business and therefore on success. In addition, many of the models in the literature on success focus only on the impact of alignment on success, on e-commerce or only on companies that adopt e-commerce, in internationalization and characteristics of the entrepreneur/CEO/manager along with other organizational and environmental factors. However, these factors of success aggregates may be relevant to agricultural business success, whether they use e-business or traditional business.

Although success is a subject discussed in the literature, it is not yet clearly developed for agribusiness sector and this can be important for the national economy. In agribusiness, Clasen and Mueller (2006)

DOI: 10.4018/978-1-7998-3473-1.ch028

analyze the impact of market characteristics on success for companies included in digital markets. The lack of research in this area and the focus of author's interest in the agricultural sector motivated this research.

This article contributes to research on success, since it develops a conceptual model of success for agribusiness, in three dimensions: growth, productivity and performance, based on a holistic approach. Having a broader view than the models found in the literature on success and suitable for companies that use e-business or not, in the specific context of agribusiness.

This chapter is structured as follows: the next section presents a synthesis review of the literature on measures for business success. The second section explores determinants with impact on business success. The third section presents the future research directions. The final section provides discussion and a few concluding remarks.

BACKGROUND: AN ANALYSIS OF THE LITERATURE ON BUSINESS SUCCESS

Success: Definition and Overview

Success is a broad term and conceptualized in different ways. According to the Oxford Dictionaries (2019), success can be understood as “the accomplishment of an aim or purpose”. Generally, success is understood as the achievement of goals and objectives for any sector of human life (Chittithaworn, Islam, Keawchana, & Yusuf, 2011; Islam, Khan, Obaidullah, & Alam, 2011). However, in the field of agribusiness enterprises, success is understood as the achievement of goals and objectives established by entrepreneur/CEO of agribusiness enterprises. Success is surviving in the business for a considerable time (Alom, Abdullah, Moten, & Azam, 2016) or a multidimensional construct that can be evaluated at the level of the system, individual or organizational (Molla & Licker, 2001).

It is possible to classify success regarding several criteria. For Chan, Sabherwal, and Thatcher (2006), success concerns the organizational performance and is measured in a single measure that incorporates various items comparing the company to competitors. Von Gelderen, Frese, and Thurik (2000) use measures of economic and personal success. Reijonen and Komppula (2007) suggest professional satisfaction and satisfied customers as criteria for measuring success. Success has a different meaning, for different companies, at different times (Bissessur & Alamdari, 1998) and can change in magnitude and over time (Trkman, 2010). It is a constant challenge for both management and researchers to measure business success (Hult & Ketchen Jr., 2001). Success has been measured in several different ways in the literature, as can be seen from Table 1.

The researcher decides to choose the enterprise growth, productivity and agribusiness performance. Unger et al. (2011) used the growth, size and profitability dimensions in their meta-analytical review. However, in this study the size is excluded because it is a control variable. In addition, agribusiness performance is added, measured through the perception of the manager. The managers' perceptions are important because they can support the future strategic decision-making for organizations, then opts to measure it through subjective measures – agribusiness performance perceived by managers. Moreover, instead of profitability the concept used is enterprise productivity. Sales per employees are more direct measures of profitability that is obtained from the Table 1. Productivity is the measure found in the literature most developed for the e-commerce endogeneity and it is represented through the sales per employees.

Table 1. Measures of success

Success	Schutjens and Wever (2000)	Von Gelderen et al. (2000)	Hult and Ketchen Jr. (2001)	Lussier and Pfeifer (2001)	Sabherwal and Chan (2001) e Chan et al. (2006)	Headd (2003)	Zhuang and Lederer (2006)	Zhou and De Wit (2009)	Lee, Jasper, and Fitzgerald (2010)	Chittithaworn et al. (2011) e Islam et al. Alternative Dimensions of Agribusiness Success: An Overview

From the previous analysis, it is justified that the success of agribusiness enterprises can be measured in several dimensions. For the purposes of this study the agribusiness success is conceptualized as growth, productivity and performance of the agribusiness enterprise. The growth and profitability dimensions are used by Unger et al. (2011) in its meta-analytical review to define success.

Nevertheless, in this study profitability is conceptualized as productivity, and is added the perceived organizational performance by managers.

Success depends, however, on the goals to be achieved. If the objective of the agribusiness enterprise is growth, then, according to the literature the growth of sales and the number of employees are important indicators for the growth of the companies. However, if the objective is productivity, the ratio sales/employees are widely used in the literature. However, if the agribusiness enterprise wants to obtain performance, the perception of managers can be an important measure. The managers' perceptions are important because they can support the organization's future strategic decision-making, then it is opted to measure it through subjective measures. No studies were found that explicitly analyze the impact of factors on agribusiness success in these three dimensions: growth, productivity and performance.

Success as Growth

Business growth is an important indicator of the economy. Furthermore, it is also used as a financial measure. Growing agribusiness enterprises are therefore successful enterprises, whereas, when they are stagnant, they are considered to be unsuccessful enterprises. In the literature, growth is measured by employment growth (Coad, Segarra, & Teruel, 2016; Nunes, Gonçalves, & Serrasqueiro, 2011; Schutjens & Wever, 2000; Sleuwaegen & Goedhuys, 2002; Zhou & De Wit, 2009), sales growth (Bahadir, Bharadwaj, & Parzen, 2009; Coad et al., 2016; Colombelli, Haned, & Le Bas, 2013; O'Regan, Ghobadian, & Gallea, 2006; Raymond, Bergeron, & Blili, 2005; Sleuwaegen & Goedhuys, 2002; Zhou & De Wit, 2009), growth of profits (Baum, Locke, & Smith, 2001) and productivity growth (Coad et al., 2016; Falk & Hagsten, 2015). As shown in Table 2, many explanatory variables are used in the growth literature.

Table 2. Papers contributing to the success literature, in terms of growth

Author name (year)	Explanatory Variables	Success indicator	Indicator Success
Schutjens and Wever (2000)	-Entrepreneur- associated factors (Thoroughness of preparation, Number of years in employed Service) - Firm-associated factors (Business partner at start-up, Monthly turnover at start-up, Employees at start-up) -External factors (Sector manufacturing / construction, Sector business services)	-Employment growth	Growth
Sleuwaegen and Goedhuys (2002)	-Age -Size -Age*Size -Capital intensity -Geographical location -Formal status -Efficiency -Sector	-Sales growth -Employment growth	
Raymond et al. (2005)	Assimilation of e-business -Funções de informação e comunicação (<i>e-communication</i>) -NE <i>intelligence</i> -Transaccional e colaborativas (CE e <i>e-collaboration</i>)	-Growth -Internationalization	
O'Regan et al. (2006)	-Internal (Innovation, Firm Ownership, Organisational Capabilities) -External (Strategic Orientation, Environment, E-Commerce)	-High growth sales	
Sapienza, Autio, George, and Zahra (2006)	-Internationalization	-Growth	
Zhou and De Wit (2009)	-Individual, organizational, environmental, growth barriers	-Growth in employment	
Coad et al. (2016)	LogSales or LogProd or LogEmpl, GrEmpl, GrInv, RDintensity, Young × RDintensity	-Growth of sales, growth of productivity and growth of employment.

Success as Productivity

Labor productivity is understood as the result obtained from the resources that have been applied. Improve the productivity concerns to maximize what can be sold/provide services maintaining the same resources. The indicator sales per employees are conceptualized in different forms in different contexts. Bertschek, Fryges, and Kaiser (2006) measure sales per employees as labor productivity. However, this indicator is used as profitability (Unger et al., 2011). However, other indicators are used to represent productivity, Konings and Roodhooft (2002) use the total factor productivity (performance), Raymond and Bergeron (2008) apply gross margin per employee, Kubota and Milani (2011) use net revenue/employee, Liu, Chen, Huang, and Yang (2013) measure through sales minus the sum of intermediate goods, water, electricity and fuel.

For Karakaya and Shea (2008), one of the reasons for companies to adopt e-commerce is to generate short-term productivity gains. Konings and Roodhooft (2002) conclude that e-business has no effect on small firms' productivity but has a positive effect on large firms. Bertschek et al. (2004; Bertschek et al., 2006) show that there is a simultaneity relationship between Business-to-Business (B2B) e-commerce and the productivity of German companies. Based on the methodology of Bertschek et al. (2004), Kubota and Milani (2011) analyzed the impact of e-commerce on corporate productivity. Liu et al. (2013) show that e-commerce has a positive impact on productivity, and the interaction between e-commerce and Research and Development (R&D) and the network externality (network effect) of e-commerce also have an effect on improving productivity.

Success as Perceived Agribusiness Performance

Success can be understood as organizational performance (Chan et al., 2006). Several theories and disciplines analyze organizational performance. Strategic research is concerned with achieving factors that contribute to the success and competitiveness of organizations (O'Regan et al., 2006). From strategic management theory, organizational behavior theory and organizational theory, and entrepreneurship models, Baum et al. (2001) develop a model to test the impact of organizational, environmental and individual factors on growth. In the view of resource-based theory, it is resources that provide organizational success (Hult & Ketchen Jr., 2001; Jebna & Baharudin, 2014; Zhuang & Lederer, 2006). In the economic literature based on the foreign direct investment paradigm, Vaatanen, Podmetina, and Pillania (2009) analyze the effect of internationalization on performance. Therrien, Doloreux, and Chamberlin (2011) develop an economic model to analyze the impact of innovation on performance. Recent study by Alom et al. (2016) identifies entrepreneurial and entrepreneur characteristics, and economic factors that influence the growth represented by performance. In the entrepreneurship literature, Davis and Harveston (2000) analyze the impact of entrepreneurial characteristics and technologies in the growth of family businesses. Von Gelderen et al. (2000) analyze the relationship between strategy and performance. Walter, Auer, and Ritter (2006) develop a model to analyze the impact of network capacity and entrepreneurial orientation on performance. Marketing literature highlights the influence of e-business on organizational performance (Migdadi, Abu Zaid, Al-Hujran, & Aloudat, 2016; Theodosiou & Katsikea, 2012; Wu, Mahajan, & Balasubramanian, 2003). Vilaseca-Requena, Torrent-Sellens, Meseguer-Artola, and Rodríguez-Ardura (2007) explain factors determining e-commerce adoption and its extent or performance. Abebe (2014) analyzes the relationship between EC adoption and performance.

Previous research has used several indicators to measure business performance. In the literature, performance is measured by different measures, both objective and subjective. In this chapter, the researcher

Table 3. Papers contributing to the success literature, in terms of productivity

Author name (year)	Explanatory Variables	Success indicator	Dimension Success
Konings and Roodhooft (2002)	-Selling on line -Buying on line -Innovation	-Total factor productivity	Productivity
Bertschek <i>et al.</i> (2004, 2006)	-Ln (ICT), Ln (K), Ln (L), industry, region, B2B	-Sales per employee	
Kubota and Milani (2011)	Ln (fixed asset), Ln (number of employees), education of employees, % of gross revenue from other units, number of units, sector, region, request of capital, exports	-Net revenue/ employees

Bertschek and Niebel (2016)	% of Emp. Using Mob. Internet, % of Emp. Predom. Using PC, % of Emp. Using Internet	-Productivity labour	

Source: elaborated by the author from different sources.

opts by measuring it through subjective measures, because these are more straightforward and easier to get than the objective and various performance aspects can be incorporated through a multidimensional construct. According to Chittithaworn *et al.* (2011) and Islam *et al.* (2011), business performance is a complex and multidimensional phenomenon, it refers to success and represents the ability of the company to generate acceptable results and actions. These results and actions should be in accordance with the organizational objectives which are intended to be achieved, and in this case it is the overall performance of the agribusiness enterprise. It is in this context that is intended the conceptualization of agribusiness performance. The managers' perceptions are considered important, because managers may support the future strategic decision-making of the organization.

FACTORS INFLUENCING AGRIBUSINESS SUCCESS

Over the years the success has been the object of many studies and a number of authors have made several contributions. Previous studies have used several conceptual models and variables to analyze the growth, productivity, and performance of enterprises. The causes of success come from organizational, environmental and individual factors. Many factors that have impact on success were found in the literature consulted between 2000 and 2019, as can be seen in Table 2, Table 3, and Table 4. Despite the different perspectives adopted, based on this literature, four factors are considered relevant to the agribusiness success model and the expectation is that they are explanatory of success: e-commerce adoption, internationalization, strategic alignment and characteristics of the manager.

Table 4. Papers contributing to the success literature, in terms of performance

Author name (year)	Explanatory Variables	Success indicator
Davis and Harveston (2000)	-Owner-entrepreneur age and education -Internet use and technology investment	-Internationalization -Organizational growth
Von Gelderen et al. (2000)	success, strategy, uncertainty and alternative determinants	-Turnover, profit, personnel, personal income, goal reaching and subjective success

Impact of E-Commerce Adoption on Agribusiness Success

The adoption of e-commerce is a strategic decision of the agribusiness enterprises that must influence the agribusiness success. This technology provides in the company the loss of focus on large sales outlets and the greatest concern with logistics (the packing in the warehouses of the orders made online and the delivery of the merchandise). Wen (2007) states that selling products through e-commerce is efficient and profitable for businesses, offers a much lower cost, easy alternative for business use and can remove intermediates in the value chain.

Karakaya and Shea (2008) analyze the reasons for companies to start adopting e-commerce. In the short term what motivates companies to adopt e-commerce are productivity gains, while in the long term it is the company's competitiveness. These authors have also studied whether these e-commerce initiatives are successful. They show the companies' satisfaction with e-commerce initiatives and that most of the companies studied by them achieve the planned return on investment (ROI).

The literature points to the positive impact of e-commerce on success. O'Regan et al. (2006) indicate that high growth companies are more likely to actively use e-commerce than companies with static or declining sales. Mei (2008) finds significant results in the relationship between the adoption of e-commerce and the growth of the company. Raymond et al. (2005) They show that the assimilation of electronic business, in terms of e-commerce and e-collaboration, positively influences sales growth. Vilaseca-Requena et al. (2007) confirm the impact of the adoption of e-commerce for the extension of e-commerce. Bertschek et al. (2004, 2006), Kubota and Milani (2011) advocate a relationship of simultaneity between e-commerce and productivity. Falk and Hagsten (2015) show evidence that increased sales through e-commerce causes an increase in labor productivity growth (performance). Abebe (2014) confirms the positive impact of e-commerce on the performance of SME (annual sales growth rate). It is also pertinent to point out, that the literature on e-commerce suggests the possible endogeneity of the adoption of e-commerce. Zhuang and Lederer (2006) Show that the performance of e-commerce influ-

ences the firm performance. More generally, Wu et al. (2003) point to a relationship between e-business and performance.

Achieving success in business through e-commerce strategies, is not only a new opportunity but a requirement (Jurado & Calabuig, 2001). Although no studies have been found on this subject in Portugal, nor specifically in the agribusiness context, several studies point to the relevance between the relationship between e-commerce and the success of companies, in different countries, both in developed and underdeveloped economies.

However, according to Bertschek et al. (2006), some companies do not opt for e-commerce probably because they predict that the cost of adoption would not be offset by the increase in productivity.

Impact of Internationalization

The internationalization strategy can positively influence agribusiness success. According to Coad (2009, p. 126), “expansion into new geographic markets can be an attractive opportunity for firm growth.” (...), “to boost sales” (...) and offers “advantages such as scale and scope economies, more market power, diversification of revenues, and the ability of spreading fixed costs such as R&D over a larger sales base”. Therrien et al. (2011) analyze the impact of exports on the performance (commercial success) in the services sector, and evidenced that to get more sales, enterprises need to enter the market early or introduce new products with high level of novelty. The authors propose that exporters are more likely to have innovative products and to market them. This may be because if an enterprise introduces a new product and has access to several markets it can spread its new product more efficiently.

Coad et al. (2016) test the impact of exports on business growth through econometric models, with growth measured through sales, productivity and employee growth, having a positive impact on all quantiles for sales growth, only for 25%, 50% and 90% quantiles for productivity and in all quantiles except 90% and 95% for job growth.

Lin, Liu, and Cheng (2011) point to a moderating relationship between internationalization and performance, with a higher level of organizational slack and attainment discrepancy.

From the same line of reasoning, agribusiness enterprises that export their products are expected to have higher sales growth, to increase productivity and sales performance and therefore a better agribusiness success. The impact of internationalization can be measured by the intensity of exports from agribusiness enterprises.

Impact of Strategic Alignment

Strategy is fundamental for enterprises to become competitive and survive in an ever-changing environment. The appropriate strategy improves the competitive position of the organization relative to competitors. According to Porter (1979, p. 143), strategy can be understood as the “building defenses against the competitive forces or as finding positions in the industry where the forces are weakest”. However, a successful agribusiness enterprise possibly needs alignment strategies to help achieve business goals.

According to Avison, Jones, Powell, and Wilson (2004), the concept of “strategic alignment” is also understood as fit (Porter, 1996), integration (Weil & Broadbent, 1998), bridge (Ciborra, 1997), harmony (J. N. Luftman, 1996), fusion (Smaczny, 2001) or linkage (Henderson & Venkatraman, 1989). However, all these definitions represent the integration between business and IT/IS strategies. Alignment is a “complex, multi-dimensional construct” (Johnson & Lederer, 2010, p. 138). Strategic alignment is a process in continuous adaptation and change (Henderson & Venkatraman, 1993). Strategic alignment

is about applying IT, appropriately and timely, in harmony with the strategies, objectives (goal) and needs of the business (J. Luftman, 2004). Strategic alignment shows us how organizations can express implementation of IT to improve performance (Bergeron, Raymond, & Rivard, 2004).

The literature on strategic alignment suggests that alignment has an influence on organizational performance, being this understood as an organizational success by various authors. In general, alignment is positively related to organizational performance (Bergeron et al., 2004; Chan et al., 2006; Naman & Slevin, 1993). Alignment presents positive results in performance in terms of sales growth, productivity and profitability (Raymond & Bergeron, 2008).

The choice of the impact of alignment on agribusiness success is due to the fact that this is important for organizational success, difficult to achieve and a major concern of management. As Naman and Slevin (1993) point out, the alignment is an important construct for the success of the company. According to Kappelman, McLean, Johnson, and Gerhart (2014), based on a survey of Society for Information Management (SIM), the main concern of management is the alignment of IT and business in the years of 2014 and 2013. However, it is the first concern, in 8 of the last 12 years, in the top 10 most important organizational IT management concerns. The authors suggest that, possibly, due to constant changes in organizations, markets, economies and technologies, alignment is a constant problem for management. However, many organizations have difficulty in achieving alignment (Johnson & Lederer, 2010).

The alignment concerns the degree to which the information technology (IT)/information systems (IS)/marketing/sales and organizational strategies adjust and contribute to agribusiness success, and corresponding how many departments of the same organization follow the same direction in pursuit of the established strategies, in terms of achieving the organization's objectives. Alignment is a process of continuous adjustment that agribusiness enterprises use to achieve the interconnection between strategies and objectives of information IT/IS or sales/commercial/marketing with the strategies and objectives of the business, whether the company works in electronic business or traditional business. In this investigation, it is expected that better alignment tends to provide better agribusiness.

Impact of Factors Associated with the Manager

In this subsection, the researcher discusses characteristics associated with the manager that appear to be relevant in the success literature. The agribusiness success is conditioned to the manager through her/his strategic decisions and is, therefore, necessary to identify her/his characteristics.

The literature presents evidence and arguments for the impact of the manager's individual factors on success. Davis and Harveston (2000) find the impact of age and education on sales growth, arguing that the aging of the entrepreneur slows sales growth, and a high level of education has a positive impact on sales growth. Lussier and Pfeifer (2001) indicate that successful owners/managers have significantly higher levels of education than those with failing firms. The same happens with results for the age of the owner. Baum et al. (2001) show the relevance of the traits, motivation and competencies of the CEO/entrepreneur for growth. Vilaseca-Requena et al. (2007) show that the performance is affected by the level of education of the manager (total sales through this channel). These authors argue that firms need highly skilled managers to lead and manage the changes that occur with adherence to electronic markets. Von Gelderen et al. (2000) find no significance in the relationship between the founder's experience and performance (success). Alom et al. (2016) show that the entrepreneur's age, education, and entrepreneurial skills positively affect growth (performance). The productivity of the agribusiness can be conditioned to who organizes the work. Therefore, it is relevant to understand the relationship between manager characteristics and labor productivity. Slavchevska (2015) shows weak evidence of

differences in productivity averages between men and women managers but conditional on the characteristics of managers.

In the literature several characteristics are analyzed. The present study uses an individual approach with emphasis on manager characteristics to try to explain the agribusiness success, through age and education. In the context of Industry 4.0, it would be expected that managers with higher education qualifications would have a positive impact on agribusiness success since higher education levels may reveal more general and technological knowledge. In addition, it would be expected that the aging of the managers slows agribusiness success because they have less knowledge of new technology and consequently less access to knowledge, and the managers need to adapt their skills for a smart farm. In addition, young managers are more dynamics to take new business opportunities.

FUTURE RESEARCH DIRECTIONS

This study offers avenues for future research. Based on this theoretical research, Negrão (2018) test a model through an econometric analysis of survey data using instrumental variables to deal with the endogeneity problem of e-commerce. However, it is suggested an empirical analysis using longitudinal data to analyze the dynamic effects of e-commerce adoption on agribusiness success. It is also suggested to carry out this study with other indicators of success, conducting this study in several countries in order to compare these results with other countries or replicate in other sectors could lead to different results.

Future investigation in this area involves further research to identify the factors critical for the success in agribusiness.

CONCLUSION

The literature review is elaborated to obtain a broad view of the subject. More specifically, it allows one to define the main concepts of this investigation, as well as the measures and determinants of agribusiness success. According to the previous studies showed in this article, the researcher develops a conceptual model of agribusiness success in Industry 4.0.

In this research, success refers to the achievement of the goals and objectives of agribusiness enterprises. This conceptual model incorporating three dimensions of success: growth, productivity and agribusiness performance. In this approach it is observed that the agribusiness success can be created from the e-commerce, the internationalization, strategic alignment, and characteristics manager. These variables are considered the fundamental criteria for the expansion of agribusiness enterprises and it is thought that it provides a complete approach of explanatory variables of the agribusiness success. In addition, to find determinants of agribusiness success is used the knowledge of several disciplines that encompasses the understanding of success to obtain a holistic view of SEA.

To measure the agribusiness success, objective and subjective measures can be used. The agribusiness success can be measured by the growth in sales that represents the enterprise growth, sales per employee that characterizes enterprise productivity and a set of items that make up the perceived organizational performance of agricultural managers.

Several general conclusions may be drawn from present chapter. Firstly, the researcher can conclude that success is a theme of interest in the scientific community that has allowed the development of studies over the years and up to the present time, thus becoming a relevant and current theme.

Secondly, it can also be concluded that there is no single measure for success, which is measured in different ways in several studies. The literature also presents several explanatory variables for success. However, there is no one way to arrive at the result. But a range of possible alternatives that are selected according to different criteria, namely, the area, the type of enterprise, the economy and the interest focus of the researcher. However, for the development of the conceptual model three relevant dimensions are analyzed and discussed: growth, productivity and performance. Moreover, it is considered to be relevant to analyze the impact of e-commerce, internationalization, strategic alignment and manager characteristics as explanatory factors of the agribusiness success. Subsequently, thirdly, it is also concluded that, the previous studies analyze the enterprises success, but with a more restricted vision. Fourthly, it can be seen that the problem of endogeneity of e-commerce adoption exists in the literature and is addressed in previous studies.

This approach has a limitation. Only agricultural companies are included because it is the interest focus of the author, however, this limits the scope, since, of course, there are other companies with an interest in success.

Based on this literature review, it is perceived that this subject is not yet properly studied, and therefore, it is proposed to investigate it empirically.

The present chapter contributes to the research on success, because it develops a conceptual model of agribusiness in three dimensions: growth, productivity and performance, whether the enterprise uses e-business or traditional business, based on a holistic approach. Success is presented a broader view than in previous models found in the literature.

KEY TERMS AND DEFINITION

Agribusiness Success: The achievement of objectives set by agribusiness enterprises.

E-Business: The exchange of information electronically internal and external to the agribusiness enterprise, fundamentally made with employees, suppliers, partners, and customers.

Growth: The growth of the agribusiness enterprise in terms of the economic or financial performance.

Industry 4.0: The fourth industrial revolution – the digital transformation of industrial markets.

Performance: The agribusiness enterprise ability to generate results and acceptable actions. These results and actions should meet the objectives of the agribusiness company.

Productivity: The result obtained from the resources that have been applied by the enterprise by the agribusiness enterprise.

ENDNOTE

- ¹ E-sales, E-Know-How, E-Collaboration, E-Service, E-commerce, Supply Chain Management SCM, customer relationship management (CRM), Electric Data Interchange (EDI) and E-Community are the most used e-business actions that can be consulted in <https://pt.wikipedia.org/wiki/E-business>.

INTRODUCTION

Authors of this chapter based their research on an authentic and proprietary mixed multidisciplinary research method that is supported by intelligent neural networks combined with a heuristics module, named the Applied Mathematical Model (AMM) (Trad & Kalpić, 2017a; Trad & Kalpić, 2017b; Trad & Kalpić, 2017c; Gunasekare, 2015). The proposed AMM is similar to the human empiric decision-making process. The AMM is supported by a real-life case of a business transformation architecture in the domain of Knowledge and Intelligence Driven Development (KIDD) that is supported by the alignment of a various standards and technologies. The KIDD is based on a real-life case for detecting and processing an enterprise heuristic algorithm for business transformation, business engineering and enterprise architecture problems. This application-driven development model offers a set of possible solutions in the form of architecture, managerial and technical recommendations, coupled with a usable framework. The proposed executive recommendations are to be applied by the business environment's architects, analysts and engineers to enable solutions to knowledge-based environments.

BACKGROUND

This work's background combines knowledge management, enterprise architecture, mathematical models, heuristics, technology management, business transformation and business engineering fields. Building a KIDD based on a Decision Making System (DMS) is today the major strategic goal for business companies, as shown in Figure 1 (Cearley, Walker, Burke, 2016; Thomas, 2015). The proposed KIDD is a generic and cross-business reasoning engine that contains basically qualitative research methods that manage sets of factors, and can be used by a Business Transformation Project (BTP). The authors based their research method on intelligent neural networks and driven development, where both methods resemble to the human brain processing. The KIDD concept is business driven and is agnostic to a specific environment, as shown in Figure 1, it is founded on a research framework that in turn is based on the industry standard, Architecture Development Method (ADM) (The Open Group, 2011a). Enterprise architecture is a methodology used to develop BTPs, requirements, architecture, knowledge modules and its technology components. The Business Transformation Manager (BTM) or an enterprise architect can integrate a KIDD in the architecture of a BTP to support its DMS system (Trad & Kalpić, 2017b; Trad & Kalpić, 2017c; Thomas, 2015; Tidd, 2006). This KIDD proposal's aim is to deliver

DOI: 10.4018/978-1-7998-3473-1.ch029

recommendations for managing aligned DMSs. The applied research methodology is based on literature review, a qualitative methodology and on a proof of concept for the related hypotheses. In a holistic knowledge management architecture, the BTM's role is important and his or her (for simplicity, in further text – his) decisions are aided by using factors within the AMM. A large set of factors can influence such an AMM, like: a) the role of the knowledge control mechanisms; b) enterprise critical success factors; c) enterprise resources; d) DMS skills; e) audit and technological conditions; f) financial predispositions; and g) security, financial and legal control mechanisms. A systems approach is the optimal choice to model such a KIDD (Daellenbach & McNickle, 2005; Trad & Kalpić, 2016a). As shown in Figure 2, the decision model interacts with the external world via an implemented framework to manage the DMS's factors and that is this chapter's focus.

Figure 1. The research framework's concept (Trad & Kalpić, 2016a)

Adapting just the underlined islands of technologies is not enough and the main problem can arise due to the lack of company's holistic agility approach, but it can be built on Knowledge and Intelligence Design Patterns (KIDP) (Thomas, 2015; Cearley, Walker, Burke, 2016).

FOCUS OF THE ARTICLE

The Research Processes

This research's main topic is related to BTPs and the ultimate research question is: "Which business transformation manager characteristics and which type of support should be assured in the implementation phase of a business transformation project?" Decision making concepts based on critical success areas are their main research component.

Critical Success Areas, Factors and Decision Making

Critical Success Area (CSA) is a category of Critical Success Factors (CSF) where in turn a CSF is a set of Key Performance Indicators (KPI), where a KPI corresponds to a single requirement and/or knowledge feature.

For a given problem, an enterprise architect can identify the initial set of CSFs for the DMS. Hence the CSFs are important for the mapping between the knowledge constructs, organisational items and DMS (Peterson, 2011). Therefore, CSFs reflect performance areas that must meet strategic goals and defined constraints. Measurements are used to evaluate performance in each CSA, where CSFs can be internal or external; like: 1) knowledge gap analysis is an internal CSF; and 2) decisions-making in real time and in minimal time is also an internal one? Ili: is internal and external one. Once the initial set of CSFs has been identified, then the BTP can use the DMS to give solutions. The proposed KIDD delivers a set of recommendations and solutions for an aligned architecture that is part of the Framework (Trad & Kalpić, 2017b; Trad, & Kalpić, 2017c).

The Framework

The BTM or enterprise architect's decisions can be made in a just-in-time manner by using outputs from various credible technology logging sources. The defined knowledge alignment strategy should assess and govern global system knowledge assets that are formalized with KIDPs. A research framework can support such an undertaking, as shown Figure 2. Unfortunately, an immense set of archaic factors can influence such a process, like: 1) the influence of knowledge management on BTPs; 2) working with complex systems; and 3) architecture standards are non-existent. A global concept and the management of KIDD approach is optimal for such complex mechanisms (Daellenbach & McNickle, 2005). In this research chapter, the focus is on the KIDD module that supports the DMS's integration. The KIDD can be applied to many BTPs and general fields in the Framework and it is a part of the Decision management module (Dm) and the Architecture and modelling module (Am). In this chapter the authors propose a set of KIDD managerial recommendations and a reusable real-world module (Trad 2018a; Trad 2018b).

Figure 2. The implementation environment that enables knowledge management

The KIDD component is managed by The Open Group's Architecture Framework (TOGAF) architecture development method's phases, where each KIDP circulates through its phases. The KIDPs contain their private set of CSFs. These CSFs can be applied to (Peterson, 2011): a) select the important knowledge management factors; b) detect the DMS's most important assets; c) estimate the actual assets of the BTP using the decision support system's interface; and to eventually take a decision on BTP's continuation; d) control and monitor the needed KIDP instances; e) upgrade the BTP's DMS knowledge management skills; and f) support the BTP management activities. The Framework or the *Environment* is composed of the following modules:

- “Sm”: for the selection management of the Framework.

- “Am”: for the architecture and modelling strategy that can be applied by the Framework.
- “Cm” for the control and monitoring strategy that can be applied by the Framework.
- “Dm” for the decision-making strategy that can be applied by the Framework.
- “Tm” for the training management of the Framework.
- “Pm” for the project management strategy that can be applied by the Framework.
- “Fm” for the financial management’s support to the Framework.
- “Gm” for the Geopolitical mind-mining to the Framework.

This chapter is a part of the research cluster that has produced many articles, literature reviews, usable items and research artefacts. In this chapter, parts of previous works are reused for the better understanding of this complex research. This work can be considered as a pioneering one, in the field of global transformation and architecture projects. For that purpose, this phase’s research sub-question is: “How would knowledge and intelligence-driven development be managed in a transformation projects?”.

The KIDD is business-driven and is founded on a research framework that in turn is based on enterprise architecture and information technology (The Open Group, 2011a).

INFORMATION TECHNOLOGY

Patterns

A KIDP expresses a fundamental structural organization or schema for system’s implementations. It offers: 1) a set of predefined knowledge templates; 2) describes their responsibilities; 3) and includes the description of the relationships between these templates. A KIDP is a schema that can be used to refine the KIDD cycle. A KIDP describes the common structure for a general design problem within a BTP implementation context by using the “1:1” concept or a holistic pattern. A KIDP is a set of idioms, where an idiom is a basic pattern that is not specific to any environment. An idiom describes the aspects of an artefact and its relationships with other BTP artefacts. KIDPs refer to patterns that are used to develop knowledge models or modules.

Agility

Global enterprise agility is achieved by combining various methodologies that promote business and technological agility to be used on various levels of the BTP, in order to unbundle the existing business environment

Figure 3. The information system’s interaction with various modules

and glue its innovated parts using a dynamic Information System's (IS) components and KIDPs as shown in Figure 3. Using a bottom-up approach, the BTM can design an IS integration concept that can handle various types of subsystems to be used in knowledge microartefacts.

Knowledge and Intelligence Microartefacts / Building Blocks

KIDD's microartefact is an instance of the KIDP building block that can interact with other BTP's microartefacts in a traced and synchronized manner and uses TOGAF's ADM to assist it in the grouping of the needed services (The Open Group, 2011a). The KIDD includes KIDP scenarios that use interactive services to make the integration more flexible (Trad & Kalpić, 2017a). DMS components support the BTP by offering KIDP instances to handle various types of knowledge endpoints. The usage of knowledge endpoints provides some of the mechanisms needed to make DMS open to internal and external requests.

The Information System Critical Success Factors

Based on the literature review, the most important IS CSFs that are used are shown in Table 1.

Table 1. The information system's critical success factors

Critical Success Factors	KPIs	Weightings
CSF_IS_Pattern	InitialPhase	From 1 to 10. 4 Selected
CSF_IS_Agility	Basic	From 1 to 10. 6 Selected
CSF_IS_KIDP	NotReady	From 1 to 10. 3 Selected

The Modules Chained Link to the Legal Aspects

This section's deduction is that standards and mapping are central for the KIDD subsystem in which they can help the unbundling process.

STANDARDS AND MAPPING

Today many standards exist and they are very advanced; these standards and their related tooling environments can help in the unbundling of the actual traditional business environments, through the execution of a bottom-up approach for BTPs. The bottom-up approach may help the business company to become a part of dynamic knowledge ecosystem; and it helps also such an environment to interconnect easily to the standardized global knowledge environments.

Choreography

Actual integration and development environments are skeletons that enclose various technologies and methodologies representing a unified implementation strategy for the company's needs. The *Environment* offers a high level interpreted language environment that can be used to enable fast business transformation develop-

ment iterations and supports its DMS. Such a development environment must respect existing standards, and its main characteristics are:

- It delivers functional language building blocks.
- It uses the company's standard development environment(s).
- It delivers the needed intelligence mechanisms.

The KIDP is based on existing proven standards as shown in Figure 4. Standard architectures are based on service oriented architecture to support KIDD. This research chapter presents a solution in the form of a proof of concept for such an approach, using existing standards and a mapping concept.

Figure 4. Existing set of standards

Mapping

Defining granularity is a very complex undertaking in the implementation phase and the complexity lies in the “1:1” mapping and classification of the discovered services in business environments with limited and optimized resources. This mapping concept uses complex messaging system to interact with the KIDP's instances. Mapping of a requirement uses a range of KIDPs that can be modelled using a heuristic function. This mapping function is based on a set of services where the KIDP's functional language consists of building services to dynamically evaluate compound expressions, according to mathematical principles. The KIDP's mathematical system model is to evaluate requirements and to deliver solutions where requirements should be well-defined, so that the KIDP enables a holistic model that can perform an evaluation that affects the final result (Neumann, 2002).

A Holistic Knowledge and Intelligence Model

The enterprise's holistic knowledge and intelligence model is a set of multiple coordinated intelligence models that correspond to various just-in-time processing schemes (Cearley, Walker, Burke, 2016). Intelligence is a holistic human mental capability that combines information management and processing that coordinate and control various mental activities. Networked information coordination manages data, extracts and correlates them in space and time to detect heuristic patterns for various types of problem solving (Gardner, 1999). These heuristic patterns and their underlined semantics are used to generate sets of weightings for possible actions that are called intelligence artefacts in this research's *Environment*. Weightings' concept enables the KIDD to build a AMM based DMS that delivers solutions in the form of knowledge values. In many cases, fast change requests may generate an important set of corresponding solutions that can be ambiguous and make the DMS actions uncertain and complex to implement. The AMM is responsible for a rational heuristic approach for

enterprise problem solving, as shown in Figure 5. The KIDD's concept is based on a holistic systemic approach to use all the *Environment's* components, being this chapter's main focus (Daellenbach & McNickle, 2005; Trad & Kalpić, 2016a). A DMS can give a company the most important competitive business advantages that may insure its future and it is not a secret that intelligent knowledge artefacts are the basis of any successful BTP (Trad, 2015a; Trad, 2015b; Trad, 2015c). Major research and advisory firms like Gartner, confirm that knowledge services will leverage business ISS' components from various enterprise departments. Gartner confirms also that services are the dominating business enablers for Fortune 500 companies who need dynamic business intelligence support (Clark, Fletcher, Hanson, Irani, Waterhouse, & Thelin, 2013).

Figure 5. The neural network enterprise architecture component tree

An Adapted Architecture

An important factor in the BTP is the role of the architecture strategy (Open Group, TOGAF 2014); where the integration of KIDPs is the base of the future IS. KIDPs are crucial for the future of any knowledge system and hence adequate architecture strategy has to be established, by the choice and application of an optimal modelling environment, as shown in Figure 6 (MID, 2014). Architecture improves the quality of solutions to individual business requirements by simplifying their design, development and maintenance; that insures their business lifecycle. The business architecture of a business transformation process is based on a hands-on holistic approach (Greefhorst, 2009).

The Standards and Mapping Success Factors

Based on the literature review, the most important knowledge CSFs that are used are shown in Table 2.

Figure 6. Archimate modelling environment (Greefhorst, 2009)

Table 2. The standards and mapping critical success factors

Critical Success Factors	KPIs	Weightings
CSF_SM_Choreography	Usable	From 1 to 10. 9 Selected
CSF_SM_Mapping	DifficultToImplement	From 1 to 10. 6 Selected
CSF_SM_KnowledgeIntelligenceModel	Synchronized	From 1 to 10. 10 Selected
CSF_SM_AdaptedArchitecture	Integrated	From 1 to 10. 9 Selected

The Modules Chained Link to the Architecture Aspects

This section's deduction is that the application of an architecture is central for the KIDD process in which the risks are mitigated.

ARCHITECTURE AND INTEGRATION

Architecture Development Method's Integration

The ADM's integration in the DMS and the BTP enables the automation of their activities, throughout all the ADM iterations. The ADM encloses cyclic iterations; where information about all its phases is logged. DMS platforms are not dedicated to any specific business and they offer: 1) knowledge assets performance; 2) reliability; and 3) knowledge assets security. The ADM is controlled and monitored in real-time and supports the KIDDs' interactions using driven developments.

Test Driven Developments

The Test Driven Development (TDD) is a manual approach and a concept where implementers design the test first and then do the implementation; whereas the Design Driven Development (DDD) that is also known as a model-first design approach, is based on best practices and it can handle all BTP requirements with the same priority for KIDD. TDD is addressed as a testing approach that supports the evaluation of the design and verifies its quality. For BTPs, the implementation phase is the most important phase and the TDD offers a maintainable design concept that returns the needed statuses which help in assessing the BTP's iterations'

outcomes. For KIDPs the question is: which type of development method is optimal, TDD or DDD or some other. Even if both development methods give the guidance for using and developing design patterns, TDD can be used in a larger sense, not in the beginning of the implementation process but as an auxiliary or even marginal support. In the case of a BTP that has large legacy implementations, the tests are developed much later. KIDP's integration needs a DDD concept that is optimal for larger environments that contain many types of technologies. This design approach is optimal for holistic projects like a BTP (Design Patterns, 2015).

Acceptance Test Driven Development

Like TDDs, Acceptance Test Driven Development (ATDD) design approach is also based on creating tests where tests represent the outcomes of the behaviour of various BTP components. In the ATDD's design approach, the BTP team creates acceptance level tests, then they implement the system. Afterwards, these test outcomes are verified to improve the BTP's implementation quality. ATDD is now a widely used synonym for Specification by Example, but the practice has existed in various forms since at least the late 1990s. Kent Beck and Martin Fowler mentioned the concept in 2015 though they observed that it was difficult to implement acceptance criteria in the form of conventional unit tests at the start of a project. But unit tests aren't the only way to write automated acceptance tests, and since at least the early 2000s, innovative teams have asked users to contribute to executable acceptance tests and have reaped the benefits. ATDD Planning is the idea that defining acceptance criteria for a feature leads to better estimates than doing a task breakdown.

Behaviour Driven Development

In Behaviour Driven Development (BDD) approach, acceptance tests offer the jumpstart for the BTP and serve as a concept for communication between the BTM, the business environment's client and the BTP's team members. In such an agile approach, acceptance tests are implemented in prose so that non-technical team-members and clients can understand the complex implementation constructs. In which there is an auto-generated mapping mechanism from prose to implementation code. The prose scenarios provide enough information to automate the extraction of the needed classes and the BTP's team-members suggest which code pieces can be extracted from the prose. The BDD enables a semi-automatic acceptance tests integration with the architecture iterations.

Design Driven Development

This Design Driven Development (DDD) that is also known as a model-first design approach is based on best practices and it handles all types of requirements with the same importance. This design approach is optimal for holistic projects like a BTP, where the designers can concentrate on building transcendent patterns.

The Architecture Critical Success Factors

Based on the literature review, the most important knowledge CSFs that are used are shown in Table 3.

The Modules Chained Link to the Knowledge Aspects

This section's deduction is that the application of a knowledge and intelligence management is central for the DMS subsystem in which the risks are mitigated.

Table 3. The architecture critical success factors

Critical Success Factors	KPIs	Weightings
CSF_Architecture_ADM	Mature	From 1 to 10. 9 Selected

CSF_Architecture_BehaviourDrivenDevelopments	Synchronized	From 1 to 10. 8 Selected

KNOWLEDGE AND INTELLIGENCE DRIVEN DEVELOPMENT

Unit of Work

In order to define an optimal unit of work for the KIDD, there is a need to align all the BTP's resources using a one-to-one mapping concept, the authors use a concrete artefact that is an object-oriented class artefact, that is represented by a class-diagram extensible Mark-up Language (XML). Such a mapping concept is based on XML and on the class artefact that insure the interoperability between all the BTP's resources. These resources can conform to one of the following artefacts' standard formats:

- The Unified Modelling Language's (UML) format.
- Design patterns and using their XML interfaces.
- The Entity Relational Modelling (ERM) using the XML Scheme Diagrams (XSD) format.
- Test Driven Development (TDD) format.
- Behaviour Driven Development (BDD) format.

Standard Patterns

Defining the unit of work for a KIDP using the one-to-one concept, serves as a concrete artefact that is a class, where mapping supports the interoperability between all BTP KIDPs who conform with the following standards:

- The Unified Modelling Language's (UML) and The System Modelling XML (SysML).
- Design patterns and their XML interfaces.
- The Project Management XML (PMXML)
- The Service Oriented Architecture XML (SoaML) and the Web Services XML (WSDL).
- Rational Unified Process (RUP).
- The Business Process Modelling Notation (BPMN) and the Business Process Execution Language (BPEL).
- The client-side frameworks like NodeJS.
- The Entity Relational Modelling (ERM) using XML Scheme Diagrams (XSD).
- Test Driven Development (TDD) and Behaviour Driven Development (BDD).
- Business Rules Management (BRM).

Knowledge Patterns

The mapping concept based on XML and on the class artefact, insure the interoperability between all the BTP's KIDD generated resources; these resources can conform to the following standards:

- The Project Management XML (PMXML) used by the project management body of knowledge (PMBOK) formats.
- The Architecture XML (ArchiXML) format.
- The System Modelling XML (SysML) format.
- Representational State Transfer (ReST) Web Application Description Language (WADL) format.
- RESTful API Modelling Language (RAML) format.
- The Information Technology Infrastructure Library (ITIL) that uses the Data Centre XML (DCML) format.
- The Control Objectives for Information and Related Technology (COBIT) using the Governance, Risk, and Compliance XML (GRC-XML) format.
- The Business Reporting XML (XBRL) format.
- The Business Process Modelling Notation (BPMN) format.
- The Business Process Execution Language (BPEL) format.
- The client side frameworks (NodeJS) format.
- The Entity Relational Modelling (ERM) using the XML Scheme Diagrams (XSD) format.
- Test Driven Development (TDD) format.
- Behaviour Driven Development (BDD) format.
- Business Rules Management (BRM) format.

Functional Environments

Today many methodologies, functional development environments, libraries and other resources exist, like for example the (Moore, 2014; North, 2010):

- Lambda expressions, also known as closures, function literals, or simply lambdas, describe a set of features defined in the Java specification request number 335.
- Functional languages, like LISP.
- Artificial intelligence and expert systems.
- Services architectures or micro architectures that support features functional environments.
- Features that are supported by Behaviour Driven Development (BDD) and Domain Driven Design (DDD) methods.
- BDD supports concepts of Neuro Linguistic Programming (NLP) and hard systems thinking.
- NLP supports neural network that forms the business intelligence application's infrastructure.

KIDP based KIDDs use BDD and NLP like interpreted scripts that can be modified, compiled and executed in real-time; such operations can be done by business professionals with no prior computer science background. That is why the authors recommend an interpretable BDD/NLP based KIDPs for the KIDD and that enhances the business intelligence by increasing computational capacities.

The Knowledge Management Success Factors

Based on the literature review, the most important knowledge CSFs that are used are shown in Table 4.

Table 4. The knowledge critical success factors

Critical Success Factors	KPIs	Weightings
CSF_Knowledge_UnitOfWork&Standards	Exist	From 1 to 10. 8 Selected
CSF_Knowledge_KnowledgePatterns	Advanced	From 1 to 10. 8 Selected
CSF_Knowledge_FunctionalDevelopment	Operational	From 1 to 10. 9 Selected

The Modules Chained Link to the Decision System Aspects

Due to the CSFs, this section's deduction is that decision making is central for the KIDDs.

INTELLIGENCE AND KNOWLEDGE BASED DECISION SYSTEM

Hard systems thinking paradigm refers to operational research, systems analysis and systems engineering; which is optimal for enterprise architecture and transformation initiatives. Hard systems thinking is a scientific approach for solving complex problems in transformation and operational situations and it replaces science laboratories experimentation environments with a set of applied mathematics models that simulate project situations and offer decisions in the form of solutions. The hard systems thinking paradigm's optimal solutions are adapted to BTP problems (Daellenbach & McNickle, 2005). BTP problems are solved by using heuristics, as shown in Figure 7 that in turn are based on critical success areas and factors.

Figure 7. Various system approaches (Daellenbach & McNickle, 2005)

Systems paradigm	Hard	Soft	Critical
Systems approaches	Systems Engineering Systems dynamics Cybernetics Systems analysis Operations Research (OR) Non-linear dynamics	Soft Systems Methodology Other Soft OR approaches: SODA, Strategic Choice Multiple Perspectives Approach	Critical Systems Heuristics (CSH) Total Systems Intervention
Sociological paradigm (Burrell and Morgan, 1979)	Functionalist	Interpretivist	Radical humanist
Habermas' classification of interests (Mendelsohn and Gelderblom, 2004)	Technical (formal societal systems)	Practical (communication)	Emancipatory
Jackson's (2001) classification of challenges	Complexity	Subjectivity	Conflict and inequality
Goal	Efficiency of system	Understanding	Critique of method Helping the marginalised/oppressed

Resources and Factors

The mapping concept is used to assemble the BTP units and resources of work. This concept is used to manage autonomic KIDD instances in the implementation phase; and it is based on a real world iterative model that maps all the DMSs resources to CSFs (The Open Group, 2011a). The BTP's DMS has to identify the initial set of CSFs to be used for the performance measurement system as shown in Figure 8.

Figure 8. The factors based framework

The Artefacts' Model

The proposed AMM nomenclature is presented to the reader in a simplified form to be easily understandable on the cost of a holistic formulation vision. The DMS uses the AMM that is formalized as shown in Figure 9.

Figure 9. The applied mathematical model's nomenclature (Trad, & Kalpić, 2017a).

AMM

mcRequirement	= KPI	(1)

Requirement	= $\sum$ mcRequirement	(4)
(e)neuron	= action + mcIntelligenceArtefact	(5)
mcArtefact	= $\sum$ (e)neurons	(6)
mcEnterprise	= $\sum$ mcArtefact	(7)
(e)Enterprise	= $\sum$ mcEnterprise	(8)
mcArtefactScenario	= $\sum$ mcArtefactDecisionMaking	(9)
IntelligenceComponent	= $\sum$ mcArtefactScenario	(10)
OrganisationalIntelligence	= $\sum$ IntelligenceComponent	(11)
AMM	= ADM + OrganisationalIntelligence	(12)

As shown in Figure 9, the symbol $\sum$ indicates summation of all the relevant named set members, while the indices and the set cardinality have been omitted. The summation should be understood in a broader sense, more like set unions.

The Decision Making System Processing

A DMS must be managed by existing audit or governance frameworks, where the BTP's team configures the types of risks to be mitigated; these risks are orchestrated by DMS actions to deliver possible solutions. The DMS actions map to the governance processes, found in TOGAF's phase G, which is responsible for the implementation of governance needed to adjust the business objectives. DMS KIDP are implemented in all

the BTP's components and the implementation of governance mechanisms should be able to identify critical risks that relate to CSFs, which might need many iterations to contain the risks; such a chain of activities can be modelled and managed by the AMM (The Open Group, 2011a; Trad & Kalpić, 2017a; Trad & Kalpić, 2017b; Trad & Kalpić, 2017c).

The Enterprise Mathematical Model

The DMS is based on the KIDD concept which in turn applies the AMM. The DMS is a part of the *Environment* that uses services to support just-in-time decision-making. The DMS, as shown in Figure 10, is based on a light version of the ADM.

Figure 10. The architecture development method

Model's nomenclature	
mcEnterprise	A micro enterprise component
mcRequirement	A micro requirement
mcArtefact	A microartefact
action (or action)	An atomic service (or neuron) execution scheme
mcIntelligenceArtefact	A set that contains: dynamic basic intelligence + governance + persistence+ traceability + data_xsd + resources
mcArtefactDecisionMaking	A microartefact_decision making entity
mcArtefactScenario	A microartefact scenario

The Enterprise AMM (EAMM) is the combination of an enterprise architecture and transformation methodologies.

The Transformation Model

The transformation is the combination of an enterprise architecture methodology like the Open group's methodology and the AMM that can be modelled after the following formula for the Transformational Model (TM):

TM = Enterprise Architecture + AMM (1).

The DMSM is based on a concurrent and synchronized infrastructure using threads that make various models run in parallel and exchange dynamically data through a mathematical choreography.

The Applied Decision System's Critical Success Factors

Based on the literature review, the most important DMS CSFs that were used are:

Table 5. The decision system's critical success factors

Critical Success Factors	KPIs	Weightings
CSF_DMS_HardThinking&CSFs	Integrated	From 1 to 10. 10 Selected
CSF_DMS_Artefacts&Processing	Synchronized	From 1 to 10. 8 Selected
CSF_DMS_MathematicalModel	Built	From 1 to 10. 9 Selected

THE MODEL IMPLEMENTATION

The Proof of Concept

The Proof of Concept (PoC) was built using the *Environment* that had been developed using the Microsoft Visual Studio .NET. The PoC is based on the CSFs' binding to a specific research resources, where the DMS was prototyped using an enterprise architecture tool. The reasoning model represents the relationships between this research's requirements, knowledge microartefacts (or building blocks) and the CSFs.

Figure 11. The Environment frontend.

The proof of concept was achieved using the development environment and the research framework that is shown in Figure 11. KIDD uses services that make calls to KIDPs as shown in Figure 12.

CSFs were selected as demonstrated in this article's tables and the result of the processing of the DMS, as illustrated in Table 6, shows clearly that the DMS is not an independent component and in fact it is strongly bonded to the BTP's overall risk architecture.

The model's main constraint is that CSAs having an average result below 8.5 will be ignored. This fact keeps the Standards Mapping and Architecture's CSAs (marked in green) that helps to make this work's conclusion; and drops the information system, knowledge management's and DMS' CSAs marked in red. It means that such a BTP will surely face failure and that the BTP must be done in two or even three transformation projects, where the first one should try to transform the information system.

Figure 12. The research flow

Table 6. The knowledge management research outcome

CSA Category of CSFs/KPIs	Influences Knowledge management	Average Result
The Information System	Built on silos/difficult to transform	From 1 to 10 5.25
The Standards and Mapping	Feasible but complex	From 1 to 10 5.75
The Knowledge Management	Difficult to implement	From 1 to 10 5.33
The Architecture	Feasible	From 1 to 10 5.00
The DMS	Difficult to implement	From 1 to 10 5.33

SOLUTION AND RECOMMENDATIONS

In this article, the authors propose the following set of architecture, technical and managerial recommendations:

- A BTP must build a holistic knowledge management concept in order to insure an efficient DMS.
- Enormous efforts must be applied to integrate underlying information system to support a knowledge management. Here is the main problem is alignment because information systems are silos.
- DMSs should replace traditional obsolete knowledge management systems.
- The architecture development method’s integration in a DMS enables the automation of all its knowledge and decision activities.
- The BTP must be separated in three transformation projects, where the first one should attempt to transform the information system.

FUTURE RESEARCH DIRECTIONS

The *Environment* future research efforts will focus on the evolution of the intelligence driven development in transformational initiatives in a cross-functional environment.

CONCLUSION

This research phase is part of a series of publications related to BTPs and enterprise architectures. This research is based on mixed action research model; where critical success factors and areas are offered to help BTP architects to diminish the chances of failure when building knowledge systems. In this article, the focus is on knowledge and intelligent systems. KIDD describes a structured inter-relationship development of various knowledge fields and the implementation of knowledge artefacts. The KIDD component's holistic integration is an important factor for the business information system's evolution. The most important managerial recommendation that was generated by the previous research phases was that the business transformation manager must be an architect of adaptive business systems.

The PoC was based on the CSFs' binding to a specific research resources and the reasoning model represents the relationships between this research's requirements, microartefacts and the CSFs. The result implies that an attempt of transformation is dangerously prone to failure. To avoid this scenario, we recommend to perform the BTP through two or even three independent transformation projects, where the task of the first ones to transform the information system

ACKNOWLEDGMENT

In a work as large as this research project, technical, typographical, grammatical, or other kinds of errors are bound to be present. Ultimately, all mistakes are the authors' responsibility. Nevertheless, the authors encourage feedback from readers identifying errors in addition to comments on the work in general. It was our great pleasure to prepare this work. Now our greater hopes are for readers to receive some small measure of that pleasure.

KEY TERMS AND DEFINITIONS

ADM: Architecture development method.

Critical Success Factors: Can be used to manage the statuses and gaps in various project plans and gives the Projects the capacity to proactively and automatically recognize erroneous building blocks and to just-in-time reschedule the project plan(s).

EMS: Enterprise knowledge management.

Environment: Is this research's framework.

KIDD: Knowledge and intelligence-driven development.

KIDP: Knowledge and intelligence design pattern.

KMS: Knowledge management system.

Manager: Business transformation manager.

Project: Business transformation project.

TOGAF: The Open Group's architecture framework.

Continuous Assurance as Digital Transformation Enabler of Audit, Risk Management, and Business Compliance

Rui Pedro Figueiredo Marques

 <https://orcid.org/0000-0001-8449-0526>

ISCA, University of Aveiro, Portugal

INTRODUCTION

The concept of Continuous Assurance began to arouse much interest when in 1999 a joint committee of the AICPA (American Institute of Certified Public Accountants) and the CICA (Canadian Institute of Chartered Accountants) took up the issue of Continuous Assurance and defined it as a set of services and technologies which enables independent auditors to provide written assurance on a subject issued simultaneously with, or a short period of time after, the occurrence of events underlying the subject (Vasarhelyi, Alles & Williams, 2010). Nowadays, the concept of Continuous Assurance is still relevant due its contribution to the current organizational context, in which there is a fierce competitiveness and a constant need for more timely, relevant and reliable information to support the decision making and achieve the strategic and operational objectives .

In this context of constant change and increasing competitiveness, seeking productivity gains and improving management tools have been a core priority. Thus, Continuous Assurance has been asserting itself and assuming an increasingly important role within organizations, with the function of management support and, in general, to ensure the economic and efficient use of resources, areas where the effects of the impact of new risk factors caused by the constant change, fierce competition and widespread access to global information are more felt (Morais, 2008).

Continuous Assurance and Auditing are sometimes used interchangeably. However, assurance is a much broader concept than auditing because whilst auditing is a systematic process of obtaining and evaluating evidences on organizational data and transactions in order to verify their compliance to standards, policies, or rules, assurance additionally includes professional services that ensure quality of information or its context, for decision makers (Soltani, 2007).

This chapter provides the concept of Continuous Assurance, its objectives and components, and a model which allows both to evaluate information systems with Continuous Assurance services and to help design the requirements of new ones. Finally, some implementations are also presented providing a comprehensive understanding the state-of-the-art and the benefits of Continuous Assurance.

BACKGROUND

Continuous Assurance is defined as the application of emerging information and communication technologies to the standard techniques of auditing, both mandatory periodic auditing and internal auditing. In that view, Continuous Assurance is a new step in the evolution of transactional auditing from manual

DOI: 10.4018/978-1-7998-3473-1.ch030

techniques to automated methods. The term “continuous” does not mean real time, but to be effective considering, respecting and being consistent with the pulse and rhythm of each organizational transaction and process (Vasarhelyi *et al.*, 2010).

Furthermore, Continuous Assurance emerges as a set of services which aims to restore the credibility of auditing, simultaneously allowing organizations to meet the requirements of regulations. Hence, it can diagnose the company’s viability and allegations of fraud and illegal acts, assessing the economy, efficiency and effectiveness of organizations (Murcia, Souza & Borba, 2008; Vasarhelyi *et al.*, 2010).

In addition, it has provided a transformation in the auditing for the maximum possible degree of automation. Given the emphasis on the digital transformation of the entire auditing system, the development of Continuous Assurance requires a revision of all aspects of auditing, namely on how data is made available to the auditor, how alerts are managed, what kind of reports are useful, and how often and to whom they are sent (Rui Pedro Marques, 2019; Vasarhelyi, Alles, & Williams, 2010)

In 2006, a survey (PricewaterhouseCoopers, 2006) concluded that Continuous Assurance triggered corporate sensitivity to its adoption because in 2005 only 35% had a continuous auditing or monitoring processes in place or were planning to develop one, and this value increased to 50% in 2006. It is interesting to observe that 56% of respondents said their continuous auditing processes include both manual and automated elements, 41% indicated their processes are entirely manual, and 3% reported having fully automated processes.

Another study by Institute of Internal Auditors and ACL (2006) also showed similar results: 36% of surveyed organizations confirmed they implemented a Continuous Assurance approach in all their business processes or simply in some selected areas, and 39% intended to implement in the near future. However, it also states that regardless of the reasons that organizations may have had to neglect the continuing auditing in the past, the recent regulations, the stimulus for real-time monitoring and reporting of financial information and the ability to automate the traditional audit methods have strongly encouraged its adoption.

The issues discussed regarding the motivations which are driving Continuous Assurance include: the growth of complexity and amount of data, the growth of electronic exchange of information and outsourcing, the integration of the value chain; reports available on the Web, and the users’ desire for reliable information and disclosed more frequently, more timely and more detailed; and the need for disclosure of updated information imposed by the Sarbanes Oxley Act (section 409) (Brown, Wong & Baldwin, 2007).

Brown, Wong and Baldwin (2007) reviewed more than 60 articles on this topic and concluded that Continuous Assurance was still a concept for most organizations and a goal for the future. The implementation of systems with continuous assurance services was residual when comparing with continuous monitoring and continuous auditing systems. These latter systems presented high levels of maturation regarding their implementation in the inquired organizations.

According to the section, in this chapter, which describes some Continuous Assurance implementations, we can see that the implementations designated as providers of Continuous Assurance services, in the period 2002-2015, were still few and with some limitations regarding the diversity of services that Continuous Assurance should be expected to offer. This shows that this area is still developing and maturing (R.P. Marques & Santos, 2017a, 2017b).

CONTINUOUS ASSURANCE CONCEPT

The concept of Continuous Assurance refers to the set of services which, by means of technology, uses the information immediately and produces audit results simultaneously with or within a short period of time after the occurrence of relevant events. Furthermore, it allows analytical monitoring of business processes. It is intended to be timely, more comprehensive, more accurate and more supportive to management than the traditional auditing (Alles, Kogan & Vasarhelyi, 2003, 2004; Vasarhelyi, Alles & Kogan, 2004).

Moreover, Continuous Assurance has provided a change in the auditing practice for the maximum possible degree of automation. Given the emphasis on the transformation of the entire auditing system, the development of Continuous Assurance requires a fundamental reassessment of all aspects of auditing, in particular on how data is made available to the auditor, how alerts are managed, what kind of reports are issued, and how often and to whom they are sent

According to IFAC (2004), the subject matter, and subject matter information, of Continuous Assurance can take many forms, such as:

- Financial performance or conditions (for example, historical or prospective financial position, financial performance and cash flows) for which the subject matter information may be the recognition, measurement, presentation and disclosure represented in financial statements;
- Non-financial performance or conditions (for example, performance of an entity) for which the subject matter information may be a key indicator of efficiency and effectiveness;
- Physical characteristics (for example, capacity of a facility) for which the subject matter information may be a specifications document;
- Systems and processes (for example, an entity's internal control or IT system) for which the subject matter information may be an assertion about effectiveness;
- Behavior (for example, corporate governance, compliance with regulation, human resources practices) for which the subject matter information may be a statement of compliance or a statement of effectiveness.

When Continuous Assurance services are running in real time, they provide the opportunity to manage transactions simultaneously with their execution or after a particular event, and even in some cases, the ability to interfere with the completion of the transaction, correcting it. When some service of Continuous Assurance points a wrong transaction, and this is corrected by the auditor, we can say the system becomes a proactive player in the processing of organizational information (Vasarhelyi *et al.*, 2004).

The terms Continuous Assurance, Continuous Auditing and Continuous Monitoring are sometimes used indiscriminately in literature. Therefore, it is crucial to understand what characterizes and distinguishes them, but mostly to understand how they can be relate to, complementing each other (Figure 1).

Continuous Assurance is a statement on the adequacy and effectiveness of controls and integrity of information. Continuous monitoring of controls is at the center of Continuous Assurance strategies; however, the audit activity ensures that management activities are appropriate and effective so that organizations have a greater level of certainty about the effective operation of controls, about risk management and about the integrity of information used for decision making (Alles *et al.*, 2003; Coderre, 2005; Kuhn & Sutton, 2006).

In turn, Continuous Auditing refers to activities undertaken to provide warranty and credibility to operations, besides giving a more timely character to issues of control and management of risk. Continu-

Figure 1. Continuous Monitoring, Auditing and Assurance (adapted from Coderre, (2005))

ous Monitoring is responsible for constantly monitoring and evaluating business transactions and their related controls, enabling a real-time view on effectiveness of controls and on integrity of transactions (Minnaar, Little & Farineau, 2008).

Evaluating the combined results of Continuous Monitoring and audit procedures, auditors can provide Continuous Assurance. However, only recently has an effort been made to understand their differences and distinguish between the concepts.

A bibliometric study (R.P. Marques & Santos, 2017b) about the evolution of research on Continuous Auditing aimed to find reasons for the very slow evolvement of research on Continuous Assurance, because author consider that Continuous Assurance represents numerous advantages for the organizational performance. Thus, they intended to understand if there is a relation between the evolution of research on Continuous Auditing and the still very low maturity levels of Continuous Assurance solutions. The study concluded that the number of publications is significantly reduced and that the slow growth of research on Continuous Auditing may be contributing to the lack of maturity of Continuous Assurance (R.P. Marques & Santos, 2017b).

CONTINUOUS ASSURANCE OBJECTIVES

The objectives of Continuous Assurance, making it really advantageous, are divided into four levels, which are difficult to define in a mutually exclusive way, but which serve to illustrate the functional dependence of Continuous Assurance on auditing (Vasarhelyi *et al.*, 2004).

Level 1 – Evaluation of Organizational Transactions

At this level, it is intended to evaluate organizational transactions, and analyze and verify the atomic actions of transactions execution (for example, movement of money or information to the level of data that compose it). With the use of corporate systems, such as ERP (Enterprise Information System) systems, it is possible to analyze, aggregate and evaluate data in order to classify and monitor organizational transactions.

At this level, input data should be tested in order to verify whether they are valid, and whether procedures in execution of transaction are consistent with the sequence of established operations, for example check whether a certain movement in the stock corresponds to a sale, to a certain bill, and whether it is in accordance with the order received. Contrary to traditional auditing, with Continuous Assurance it is possible to do this check in real time due to automation and integration of audit procedures. This transaction control can use the formal specification of workflow of processes defined in the ERP systems as a standard behavior of transaction. Thus, it is possible to verify whether transactions have been executed in compliance with all provided steps to foresee the flow of transactions, and whether these are missing or failing.

Level 2 - Compliance of Performed Operations

At this level it is intended to ensure that procedures applied in the execution of organizational transactions are appropriate (for example, are consistent with the rules, norms, or standards set by the organization or by external regulatory entities).

The procedures of this level use comparison with standards in order to verify the application of these rules and standards, and if any inconsistency is found, the situation will be forwarded to the auditors or other responsible person for consideration. Although in this latter case the resolution of the problem is not guaranteed in real time, this selectivity will allow greater efficiency in the auditors' tasks.

Level 3 - Quality of Estimates and the Consistency of Aggregate Data

In some businesses, estimates and forecasts are often used because the measurement or direct determination of some information is difficult and expensive to obtain. For example, the percentage of completion of a work is not always easy to measure, and therefore, must be estimated.

Even if an organization does not automatically generate an estimate, continuous assurance services can use their own formal models to ensure in real time that the estimate used is acceptable. Obviously, the creation of a formal model of an accounting estimate is not a simple proposition and can add significant costs to the development of Continuous Assurance. A simple and economical alternative is to use a formal model to automatically get an estimate, then the auditor's task will be reduced only to verifying the acceptability of this model, which can be done only once and off-line, based on knowing whether the used parameter values in model are reasonable.

This level of Continuous Assurance includes automation of analytical procedures based on internal and external parameters. The use of analytical procedures in an automated system of Continuous Assurance increases efficiency and effectiveness of auditing.

Level 4: Evaluation of Organizational Decisions

The auditing carried out by using ERP systems and advanced financial instruments must incorporate complex and high level assessments, which are especially important for decision making. Such judgments may have to deal, for example with the relevance of contingencies, the extent of related-party transactions, the boundaries of corporate systems, and the nature of the relationships across the value chain. Continuous Assurance and the current analytic technology allow the extensive gathering of exogenous evidence, which provides crucial input into these judgments. Continuous Assurance may use, for example data warehousing and data mining as tools that facilitate automation of some of these decisions, improving the quality of high-level decisions and decreasing the audit risk.

CONTINUOUS ASSURANCE COMPONENTS

Continuous Assurance is divided into three distinct components, but complementary (Vasarhelyi *et al.*, 2010):

- *Continuous Controls Monitoring (CCM)* consists of a set of procedures to monitor the operation of internal control mechanisms;
- *Continuous Data Assurance (CDA)* verifies the integrity of the data circulating in organizational information systems;
- *Continuous Risk Monitoring and Assessment (CRMA)* measures the risk dynamically and allows to sustain an auditing plan.

Continuous Controls Monitoring

CCM is a set of emerging technologies which monitors controls in ERP systems and other applications in order to improve business governance, monitor and verify access and transactional rules, and to automate audit processes. CCM assists the business in: reducing business losses from fraud or failure; following rules or procedures which govern transactions; and improving performance through monitoring and auditing of the controls implemented in the systems (Caldwell & Proctor, 2010).

Caldwell and Proctor (2010) identified many important CCM functionalities, namely controls monitoring functions, exception and remediation management, reporting and analytics, and workflow. With these functionalities, CCM adds value, in an organization, to risk management and to the following compliance initiatives:

- lowering compliance costs - CCM reduces the cost of auditing by eliminating some manual sampling and minimizing the time it takes to gather documentation;
- improving financial governance - CCM can increase the reliability of transactional controls, improve auditor trust and increase the effectiveness of antifraud controls;

- improving operational performance - CCM controls, such as those that monitor duplicate payments, incorrect discounts or misapplied warranties, go beyond what most people consider compliance.

A study (R.P. Marques & Santos, 2017a) concluded that research in Continuous Monitoring is still very scarce. Considering that this, together with Continuous Audit, is one of the essential components of the Continuous Assurance, it is possible to establish the relationship between this research scarcity and the slow pace in the development of complete Continuous Assurance solutions. In fact, we can only contribute effectively to the development of Continuous Warranty when all its components have been properly studied (R.P. Marques & Santos, 2017a).

Continuous Data Assurance

CDA has been a powerful tool in organizations, particularly in financial and accounting areas, to extract data from organizational databases and applications in order to make analyses at the transactional level and to provide more detailed assurance. It has the main objective to change the traditional vision of data auditing in which reports were prepared and audited only once a year; sampling was used rather than examining the entire population; data were analyzed at the trial balance level using ratios.

This aggregation and analysis at a higher level than the transactional level has been a cost and capability-based limitation rather than the ideal process for assurance. Thus, CDA can continuously monitor transactions, comparing their characteristics with expected behaviors, thus identifying anomalous situations. When substantial divergences occur, alarms will be triggered and routed to the respective stakeholders (Vasarhelyi *et al.*, 2010).

To implement transaction verification it is necessary to specify data validity, consistency and referential integrity rules which are then used to filter data. These rules aim to detect and remove two types of data errors: data integrity violations (for example, invalid purchase quantities, receiving quantities and bank check numbers) and referential integrity violations which are largely caused by many unmatched records among different business processes (for example a payment made for a non-existent purchase order).

Continuous Risk Monitoring and Assessment

CRMA is the process by which organizations address the risks attaching to their activities in pursuit of organizational objectives and across the set of all their activities. Besides, CRMA involves: measuring risk factors continuously, integrating different risk scenarios into some quantitative framework, and providing inputs for audit planning, i.e. it engages risk assessment, risk evaluation, risk treatment and risk reporting. The organizational risk management approach is intended to align risk management with business strategy and embed a risk management culture into business transactions (Collier, Berry & Burke, 2007; Vasarhelyi *et al.*, 2010).

INFORMATION SYSTEMS WITH CONTINUOUS ASSURANCE SERVICES

Marques, Santos and Santos (2013a) proposed a model composed of three dimensions and one requirement, which aims to evaluate an information system with Continuous Assurance services, and which intends to be regarded as a referential set of requirements when developing this type of information

systems. The authors used the Delphi method to validate the model in order to ensure the relevance of inclusion of these dimensions and requirement and also a set of metrics to be included in each dimension and requirement (Rui Pedro Marques, Santos, & Santos, 2016). Furthermore, this model was successfully used in a more comprehensive research project (Rui Pedro Marques, Santos, & Santos, 2015).

It is composed of the dimensions Monitoring, Compliance, Estimation and the requirement Reporting, which comprise all objectives and components of a system with Continuous Assurance services (Rui Pedro Marques et al., 2013a, 2016):

- Dimension ‘Monitoring’ relates with the objectives of level 1 and the component CCM. In this dimension, the following metrics may be found to assess whether the system can: monitor the various operations of a process as soon as they occur; identify an irregular (unforeseen or inconsistent) operation as soon as it occurs; verify whether the operations were processed at all the previous steps as required; detect lack of operations; and assess the continuity and completeness of transactions.
- Dimension ‘Compliance’ includes the features of the component CDA and the objectives of level 2. The metrics associated to this dimension aims to assess whether the system can: recognize which known execution pattern was or has been followed by each organizational transaction monitored; ascertain which rules, conditions and procedures were fulfilled and unfulfilled in the organizational transactions monitored; detect potential errors; inhibit inappropriate events or behaviors; and help compliance with existing laws, policies, norms and procedures.
- Dimension ‘Estimation’ covers the objectives of level 3 and the functions of the CRMA component. The metrics of this dimension assess whether the system can: estimate, given the current situation, what the possible results of the organizational transaction execution will be; and determine the execution pattern, or a set of execution patterns, which will be possible to be followed by the organizational transactions monitored, according to the current status of execution.
- Requirement ‘Reporting’ includes the features of all components and the objectives of all levels. The metrics of this requirement must assess whether the system can: report the results of the monitoring of transactions; notify the results of the verification of compliance; inform the results

Table 1. Dimensions of the model and their metrics

Dimensions and Requirement	Metrics
Monitoring (dimension)	– Real-time monitoring of operations – Real-time identification of irregular operations – Real-time verification of processing of required operations at all previous steps – Real-time detection of lack of operations
Compliance (dimension)	– Recognition of execution patterns – Ascertaining of fulfilling of rules – Detection of potential errors – Verification of compliance of existing policies
Estimation (dimension)	– Estimation of possible results – Determination of possible execution patterns which are likely to be followed
Reporting (requirement)	– Real-time presentation of the executed operations which were monitored – Real-time presentation of execution patterns which are being followed or are likely to be followed – Real-time presentation of the compliance verification in transactions executions – Real-time presentation of the risk estimated on determining possible execution patterns – Real-time alert for irregular situations in monitoring, compliance verification and estimation of negative results

of estimation; and alert users of irregular situations in monitoring, compliance verification and estimation of negative results.

Table 1 concisely summarizes this model, presenting quantitatively measurable metrics for each dimension and requirement.

CONTINUOUS ASSURANCE AS DIGITAL TRANSFORMATION ENABLER

Some solutions in the field of Continuous Assurance have been made available in the market and are mostly developed by well-established CAAT (Computer Assisted Auditing Techniques) manufacturers and vendors, which begin to position themselves in this still emerging market. Despite regarded as Continuous Assurance solutions by vendors, these products focus more on the CDA component. The implementation of CCM solutions is very complex due to significant differences in the types of business objects, process configurations and controls and then it is not cost-effective. Thus, these solutions have developed some very specific CCM modules targeted at specific enterprise systems. Such modules are quite laborious since they require customization for each new enterprise system (Vasarhelyi *et al.*, 2010).

An organization in the steel industry with 234 industrial and commercial units, present in 10 countries and with shares in New York Stock Exchange, was forced to implement measures of Continuous Assurance in accordance with SOX requirements. After these measures, all processes had to be documented and information started to be disclosed in time and with their integrity ensured and it held the participants responsible, inhibiting the occurrence of fraud (Hargadon & Fanelli, 2002).

Siemens has made an effort in this area and it has successfully experimented some aspects of Continuous Assurance, namely to ensure the integrity of its ERP systems and their automated modules with audit functions. Siemens's project proposes a methodology to monitor and evaluate the daily configuration of various settings of existing controls through the use of CCM, because about 68% of its audit activities could be fully automated. Thus, an independent system was developed for interacting with read-only operations with the existing information systems and for reporting system and alarms in case of emergency. These implementations have ensured the effectiveness, efficiency and a timely character to the audit procedures. (Alles, Brennan, Kogan & Vasarhelyi, 2006; Alles, Kogan & Vasarhelyi, 2008). The use of CCM at Siemens Financial Services enabled significant improvements in the average exception rate, through the testing and monitoring of performance analytics (e.g. input checks, validity checks, and compliance with regulations and internal policies). In some departments, the reduction in the average exception rate was over 20% in the first year of implementation (Medinets, Gross, & Brennan, 2015).

Also according to Vasarhelyi *et al.* (2010), one of the biggest banks in Brazil, with more than 1400 branches, has implemented measures for Continuous Assurance, proving the viability and benefits of these measures. This institution has a CDA, a system which daily analyses more than five million accounts and generates about six thousand alerts a month. This system aims to increase productivity with efficiency and quality and its mission is to assess the risks and controls automatically and continuously in order to identify exceptions, anomalies, trends and indicators of risk; advise about controls, risk assessment; and contribute to the corporate governance. These features include all products, processes and services which enable data extraction and analysis. The taken approaches are of detection (routines to detect possible errors), of deterrence (routines to inhibit inappropriate behavior and events), financial (routines to reduce or avoid losses), and of compliance (routines to ensure compliance with applicable laws, policies and standards).

Recently, an innovative solution was developed to implement Continuous Assurance services in information systems applicable to any business process, regardless of its type, dimension, business area or even its information system support technology, supported by an ontological model at an abstraction level that guarantees that contextual independence. The results analysis from an implementation of this solution allowed to ensure the feasibility and the effective use of the solution (R. P. F. Marques, Santos, & Santos, 2013; R.P. Marques, Santos, & Santos, 2015).

The latter implementation showed to provide full services of Continuous Assurance, because it is able to record the operations which compose the organizational transactions and which are performed in the operational information system; enables the instantiation of risk profiles associated with organizational transactions; is capable of recognizing risk profiles, which were followed by the already concluded organizational transactions; is capable of determining possible risk profiles, which are being followed or likely to be followed by organizational transactions still in progress; provides the presentation of the executed operations, which were monitored; provides the presentation of execution patterns, which are

Figure 2. Conceptual architecture of the solution proposed by Marques et al. (2015)

being followed or are likely to be followed and the results of the compliance verification in the execution of transactions; provides the presentation of risk estimated on determining possible execution patterns; is able to alert for irregular situations in monitoring, compliance verification and estimation of negative results; and provides its functionalities in real-time. (Rui Pedro Marques et al., 2015)

Figure 2 schematically represents the conceptual architecture of this solution. The system is connected to the operational information system in which internal control mechanisms are incorporated in order to monitor operations and data related to the transactions we intend to control (Rui Pedro Marques, Santos, & Santos, 2014). The Real Online Transaction Repository (component A) manages and stores this information from the internal control mechanisms. The component B illustrates the risk profiles repository of the organizational transactions to be monitored and audited (Rui Pedro Marques, Santos, & Santos, 2013b). These risk profiles represent different ways, negative and positive, to execute transactions. The component C is the module intended to be able to compare the various records in the risk profiles repository and determine which profile is being followed by running each transaction, according to the information received by component A (Rui Pedro Marques, Santos, & Santos, 2018). Finally, the results from the comparison module are reported the users of the system (component D), enabling the viewing of the current and historic state of controlling of the audited transactions.

Finally, another study (Barros, 2018) concluded that the degree of importance assigned to a Continuous Assurance service by the internal auditors is superior to the degree of use of those services. Authors affirm that some Continuous Assurance services are already implemented in medium and large companies and present in the professional life of the internal auditors. However, they also state that there is still a lot of work to be done to ensure that the Continuous Assurance service is fully implemented in the organizations. Despite the relatively slow evolution, it can be stated that specially in the medium and large companies, most of the internal audit professionals are aware about the importance of implementing a Continuous Assurance system and that the use of some of its services is already somehow established in their daily routines.

FUTURE RESEARCH DIRECTIONS

The limitations of Continuous Assurance that can be found in the chapter are likely to be the next future research topics in this area. A major limitation is in the CCM, because its implementation is complex due to the variety of control mechanisms it has to monitor in different business processes and contexts. A CCM which can be independent of the business processes and contexts was already implemented (Rui Pedro Marques et al., 2015) although it is still very dependent on control mechanisms and on the initial system customization, which is a time-consuming and very hard task. Guerreiro, Marques and Gaaloul (2016) present a high-level conceptualization of an evolvable risk-based approach capable of self-learning the needs of monitoring, based on the continuous observation of business processes and of the results of continuous monitoring (approach with feedback control). This type of approaches has promising results and may be a future research direction.

Furthermore, a conceptualization of a model to assess the maturation of Continuous Assurance seems to be relevant to evaluate the services provided by the emergent solutions and, simultaneously, to follow the evolution of Continuous Assurance. Considering that reporting plays a crucial role in continuous assurance, there is also a need to propose innovative dashboards, validated by audit experts, to increase the efficiency of the use of outputs of such systems.

Finally, another future research direction may include assessing the impact of blockchain (Dai & Vasarhelyi, 2017; Kokina, Mancha, & Pachamanova, 2017) and robotics (Moffitt, Rozario, & Vasarhelyi, 2018) on continuous assurance.

CONCLUSION

Although Continuous Assurance is not a concept firmly established yet, it is clear that it is maturing both in practice and in research because of its proven benefits in various organizational branches. In the public sector, the health service, social security institutions, tax administration, banking can be stated as examples. In the private sector, any organization can benefit from the implementation of Continuous Assurance, although those with greater resources are more able to bear it and keep it, for example, the areas of banking and telecommunications.

Furthermore, recent researches have proved the feasibility of implementation of information systems with full services of Continuous Assurance, covering all components and levels of objectives, to any business area and any type, dimension and nature of business process, providing very positive outcomes to the operational performance and accountability of organizations.

KEY TERMS AND DEFINITIONS

Continuous Assurance: Set of services which, making use of technology, uses the information immediately and produces audit results simultaneously or within a short period of time after the occurrence of relevant events.

Continuous Auditing: Activities undertaken to assess the business compliance to rules, policies, or legislation, providing warranty and credibility to operations.

Continuous Monitoring: Process responsible for the management of internal control mechanisms in order to ensure their effectiveness, allowing to obtain timely information about transactions.

The Risk Assessment Enhancement Process at the Federal Deposit Insurance Corporation

University of Evansville, USA

INTRODUCTION

Government agencies often face increasing challenges to collect, process and analyze voluminous data from corporate and individual filers. Specifically, supervisory banking institutions have appreciated the imperative role of technological innovations to facilitate data processing to analyze business and financial risks of their bank filers. With the advancement in electronic reporting technologies and the intricacies of risk management process, bank regulators are challenged by the complexity of such process to provide better data that will support and inform the bank examination process. Bank regulators interested in the development and expansion of the risk assessment systems face some technical and organizational problems. Such problems are caused by the inherent complexity of the data in bank filings, the proliferation of compliance requirements, and the growing data security concerns, which can all hamper the pace of system development and the generation of quality data (Burton & Seale, 2005; Raghavan, 2007). One of the popular methodologies that have been adopted to overcome such challenges is the Unified Rational Unified Process (RUP®) system development methodology.

In this chapter, a leading government agency represented by the Federal Deposit Insurance Corporation (FDIC) has adopted the RUP® methodology to enhance its risk assessment process. The FDIC's decision was driven by the practicality and agility features of the RUP® and its compatibility with the agency's reporting systems. Specifically, the agency decided to use RUP® to develop its existing Examination Tool Suite (ETS), which supports the main structure of the risk assessment process at the agency.

The RUP comprises four important phases, which characterize the process of developing a system from inception to transition into the target user community. These phases have been explained in this chapter in the context of the FDIC's ETS development process. To better understand the agency's motivation to develop its risk assessment process, the chapter discusses the main characteristics and functions of the ETS application. The agency's main motivation to develop ETS application and choose RUP® to accomplish that goal are also explained. The rest of the chapter discusses the project development phases, challenges, realized benefits and learned lessons. Practical implications and concluding remarks are presented at the end of the chapter.

BACKGROUND

Organizations can select from a variety of software development methodologies. A software development methodology defines the process, documentation and techniques that could support the system

DOI: 10.4018/978-1-7998-3473-1.ch031

developers to create and implement a new information technology system (Avison & Fitzgerald, 2006). One of the most notable methodologies in software implementation and development is the Rational Unified Process (RUP®). RUP is an agile process framework that has been created by Phillippe, Kruchten, Ivar Jacobsen and others at Rational Corporation and used in many software implementation projects (Jacobson, I. Christenson, M., Jonsson, P. & Overgaard, G., 1990; Kroll & Kruchten, 2003). The agility component of RUP® framework provides a detailed description of the process requirements which are needed for an agile methodology, often characteristics by its adaptive, straightforward, incremental, and cooperative features (Callahan, 2006). In addition, it is a software engineering process framework that could be used as a best practice for supporting software development projects. The structured approach of RUP® allows system developers to assign tasks and create milestones for deliverables based on predictable schedule and budget (IBM, 2006).

The Rational Unified Process methodology has four advantages. First, the RUP® improves the productivity of the software development team. The process is well-structured and document and offers and allows the development team members to have quick access to the process guidelines and templates, which creates a strong knowledge base for all the members (RUP, 1998). Second, RUP® methodology provides a framework that can be adapted according to the size and complexity of the operating system and the experience and skill of the development team (Jacobson, I., Booch, G. & Rumbaugh, J., 1999). Third, the use of the RUP® methodology is based on utilizing key best practices, which include the iteration of software development and the ability to verify the software quality, monitor changes, and develop risk mitigation strategies (RUP, 1998). Fourth, RUP® elevates the level of system abstraction by reusing existing assets, which subsequently reduce its complexity and project documentation (Geambasu, C., Jianu, I., Jianu, I & Gavrilă, A., 2011).

On the other hand, RUP® has some disadvantages. The increased level of project complexity amplifies the burden of financial, operational and human resources of the organization. The iterative nature of the framework could cause project delays because each phase of the project has to be done methodically and consistently, which could make the project less affordable and more difficult to manage (Callahan, 2006).

Previous research indicates that there are several factors that affect an organization's decision to adopt RUP® methodology. Geambasu et al. (2011) emphasize the importance of clarifying the initial systems requirements with the client prior to the deployment of development work to fulfill all the client's needs and preferences. The researchers also suggest that the first phase, Inception, provides an opportunity to draw realistic initial estimation of costs and development time of the project. In addition, the researchers report that the incorporation of required changes and the production of multiple 'versions' of the system resulting from iterations during the development process are important factors that could more or less expedite such a process. Finally, the authors suggest that the system development costs, the duration of the delivery time of the final version of the system, the system complexity and communication between the client and system developers are significant factors that companies should consider carefully before adopting RUP® methodology.

The RUP System Development Life Cycle process and Phases is presented in Figure 1: inception, elaboration, construction, and transition. Each phase contains one or more iterations that cover a series of disciplines. A discipline is "a collection of activities that are related to a major area of interest" (IBM Corporation, 2006). Figure 1 depicts two axes. The horizontal axis represents the time and showcases the dynamic evolution of the process as it is performed. It is expressed in terms of phases, iterations and milestones. The vertical axis represents the description of the disciplines in terms of activities and workflows.

Figure 1. RUP System development life cycle process and phases

Source: FDIC RUP Web site.

Inception Phase

The main goal of this phase is to achieve agreement among all stakeholders on the main objectives of the project. During this phase, the organization should assess and address the project's business risks, requirements, and constraints before proceeding to the next phase. Also, the organization should evaluate the project's business case based on its cost, scheduling and profitability.

Elaboration Phase

The goal of this phase is to create an architectural foundation for the system that will define its design and implementation efforts. The architecture is created based on identifying the most important system requirements and plans for mitigating risks and predicting costs. In this phase, decisions are made with an understanding of the system scope, functional and non-functional requirements such as performance requirements. Also, an executable architecture prototype is created in possibly multiple iterations depending on the system scope and size. Elaboration is arguably the most prominent phase in the RUP process. Decisions are made in this phase to determine the stability of the architecture, the adequacy of risk mitigation procedures, and the acceptance of the actual resource expenditure versus planned expenditure. Therefore, the outcome of the elaboration phase will determine whether an organization is committed to move to the next phase.

Construction Phase

The goal of this phase is to clarify the remaining system requirements and complete the system development based on the previously created architectural foundation. The emphasis is on the manufacturing process, resource management, schedules and quality optimization. In addition, the organization completes the product development and testing against pre-determined evaluation criteria. This phase entails a transition from the development of intellectual property, which characterized the inception and elaboration phases to the actual development of the deployable products during construction and transition phases.

Transition Phase

The focus of this phase is on ensuring the availability of the new system through the distribution channels and sales teams to the end users. User feedback is solicited through “beta testing” to configure the installation, resolve usability issues and develop new releases. In addition, the organization should prepare user-oriented documentation, offer training and product enhancement and fix potential bugs.

The Pre-Developed ETS Application

The Examination Tool Suite (ETS) application supports the FDIC’s bank examiners and risk assessment personnel in performing the following supervisory tasks (FDIC, 2015):

- Risk management examinations.
- Bank Secrecy Act/Anti-Money Laundering (BSA/AML) examinations.
- Reports of investigations.
- Specific information technology, trust, government security dealer, municipal security dealer, and registered transfer agent examinations.

The ETS imports information from multiple sources (FDIC, 2015). The first source is financial institutions and banks. The FDIC’s risk assessment personnel often request full or sub-set information on the bank’s asset portfolio, which can be provided via the FDIC portal (FDIC-connect) or encrypted memory stick. The data can be easily loaded into ETS application by authorized FDIC staff. Upon receiving bank portfolio information, the FDIC examiners edit the information to meet the specific requirements of the examination process. The second source of information is the Central Data Repository (CDR). The CDR is a central repository that is operated by the Federal Financial Institutions Examination Council’s (FFIEC’s) for the purpose of collecting, storing and distributing Call Report data. The Call Report is known as the Consolidated Reports of Condition and Income, which is submitted to the FDIC every quarter to monitor the bank performance and risk profile¹. The CDR provides Call Reports and Uniform Bank Performance Reports (UBPRs) to the ETS. The third source of information is the Corporate Business Information System (CBIS), which is operated by the Federal Reserve Board. The CBIS is a data warehouse facility that provides users with the FDIC’s financial data that has been sourced from banks and lending institutions. Similar to the CDR, bank data is also derived from the Call Report and uploaded to the ETS for examination purpose. The fourth source of information is the ‘DSC Hours’ system, which is an internal FDIC system. This system collects and stores the FDIC’s examiners information, which include their names, position titles, grades, department ID, and working hours. The fifth source is the Interagency Examination Repository (IER)². The IER provides historical bank examina-

tion data which include shareholder and management (including titles, occupation, attendance) to ETS via Report of Examination (ROE) service. The sixth source of information is the Structure Information Management System (SIMS). The SIMS provides publicly available bank information, which includes its name, certificate number, branches, CEO, and web address. The information is uploaded into ETS to support bank examination process. The last source is the Virtual Supervisory Information on the Net (VISION). VISION provides ETS with statistical information, metrics for analyzing insured banks, and examination-related information. Table 1 provides a sample of examination data from year 2015 to 2017.

Examination Tool Suite Application: Background

Prior to the development of the application, the ETS was used primarily as an Automated Loan Examination Review Tool (ALERT) to support the Risk Management (RM) Division and examiners at the FDIC. The RM Division is responsible for examining and supervising state-chartered, non-federal reserve member banks to ensure that they meet the compliance requirements. As part of the examination process, the RM examiners use the Call Report to perform an in-depth analysis of a bank's loan portfolio quality to determine any potential risk to the FDIC insurance fund. The examination process also involves the processing of personally identifiable information of individual and commercial borrowers. Ultimately, the FDIC generates a Report of Examination (ROE), which includes a risk review of individual bank's compliance system focusing on the lending, deposit and investment activities.

The Risk Management personnel and bank examiners often use the ETS application every quarter to review changes in the quarterly Call Reports, manually interpret those changes, and update the application accordingly. In the past, the RM personnel had to wait certain cycles for such updates. By the time ETS was updated, the data had become too outdated for generating the FDIC's Report of Examination (ROE). The FDIC wanted to develop a better solution to expedite the publication of the Call Reports. In addition, the agency sought to provide the examiners with instant access to Call Report and Uniform Bank Performance Report (UBPR) data, analyze information in real-time, and reduce the delivery time for updates to ETS each quarter. Consequently, the generation of the FDIC's ROE will be expedited too (Montoya, 2016).

FOCUS OF THE CHAPTER

FDIC'S Motivation for ETS Development

The Federal Deposit Insurance Corporation faced the challenge of using multiple systems (e.g. GENESYS, Interagency Exam Repository)³ to analyze banking data for risk assessment purpose (CSBS, 2012). This challenge was coupled with the difficulty of eliminating redundant data, updating the current data, and securing remote and easy access of banking information for examination purpose. The agency opted to elevate the functionalities of one of its existing bank examination tools, known as the ETS-Supervisory Application Generating Exams (ETS-SAGE) application. Specifically, the development project was undertaken to achieve the following objectives (FDIC, 2015):

- Decrease maintenance expenses by reducing technical complexity and the number of systems that the FDIC examiners have to use to perform their job.
- Eliminate data redundancy and duplicative data entry.
- Improve ease of access, reporting, and data accuracy.
- Reduce risk and improve the security of examination data.
- Safeguard sensitive examination information by strengthening data security controls.

In addition to those objectives, the FDIC implemented multiple administrative and technical control measures to prevent unauthorized access and misuse of bank data. These controls included the installation of the newly developed ETS application on laptops and desktops which are compliant with FDIC's IT security policies and subject to regular vulnerability/penetration testing assessments. Finally, all the FDIC examiners would be required to pass background checks and comply with the FDIC security and privacy policies. Also, examiners only have access to data on a "need to know" basis (FDIC, 2015).

FDIC's Rationale for Adopting the RUP® Framework

The FDIC adopted the Rational Unified Process® (RUP) as the agency's system methodology for developing the ETS-SAGE application (Rational Software, 1998). The RUP® framework was used to meet specific requirements of the project based on the size and complexity of the data in the bank filings. Through the application of the RUP® Framework, the agency supported the practice of shorter software delivery which entails the delivery of small and short increments of implementation phases. The RUP® framework was also selected for its practicality that would allow the project implementers to develop,

test, style each feature and phase in the project before moving on to the next phase. Lastly, the framework allowed the system users to be involved in the project development and testing as the users' feedback is solicited.

SOLUTIONS AND RECOMMENDATIONS

The Application of the RUP® in the FDIC Context

The Inception Phase

During the inception phase in early 2012, the FDIC developed a detailed understanding of the needs and uses of the ETS application. A Project Initiation Review Committee met with the ETS project managers to review the start-up of the project, help establish priorities, resolve potential conflicts, and plan key activities to successfully initiate the project (FDIC, 2014). The project managers worked with a software vendor to develop the ETS application that would recognize interfaces with other systems. In addition, the managers worked on identifying key risks, determining acceptance criteria, capturing the reporting requirements, and developing costs and schedules.

The Elaboration and Constructions Phases

During the elaboration phase and at the end of 2012, the ETS software vendor built a prototype of the ETS to ensure that the proposed solution would support the ETS requirements at a reasonable cost and within an appropriate timeframe. At the end of this phase, an initial testing was performed to identify and mitigate emerging risks. Detailed iteration plans for the construction phase were laid out and a comparison between the actual and planned expenditure was performed. During the construction phase, the software vendor and the FDIC completed the analysis, design, development, and testing of the ETS's functionality (FDIC, 2014).

The Transition Phase

During this phase, a final testing of the ETS was performed and adjusted based on user feedback. Testing was performed using simulation, which involved the FDIC examiners and a sample of filer banks. At this phase, the user feedback became prominently focused on fine-tuning the configuration and installation of the ETS.

Project Challenges

The U.S.'s Government Accountability Office has identified the following common challenges that meet federal agencies adopting the RUP® framework in technology development projects (GAO, 2012):

- Project members at federal agencies often have difficulty collaborating closely. This is due to the fact that staff members are used to work independently and are less willing to provide consistent feedback regarding their work to their customers preferring to offer feedback on finalized outcome(s).

- The creation of cross-functional teams in federal agencies is a common challenge. Federal employees tend to be specialists in a specific functional area. Consequently, a team member could represent system users but may not be experienced in identifying all the users' needs.
- Some federal employees face challenges in providing timely and frequent feedback due to the typical fast pace of technology-based projects. If a project faces a critical issue, team members often stop their work to address it rather than make a decision and proceed to the next step.
- Project members often take long time to be familiar with new automated tools to support project planning. This is often due to the fact that there is an apparent delay in purchasing, installing, and learning to use such tools.
- Creating and maintaining technical environments in federal agencies poses another challenge. This is especially relevant to certain projects, which require the technology development and testing to be executed concurrently. The iterative nature of RUP®-based projects requires a sophisticated coordination of staff members and resources.
- During the execution of project, compliance reviews are difficult to perform within an iteration. Such reviews are expected to be performed within short and fixed timeframe, but that is often a great challenge in federal agencies as they follow slow-paced schedules.
- Rather than providing timely feedback on the current state of projects as expected in RUP® methodology, federal agencies prefer to report status on milestones. Upon reporting on milestones, federal agencies interestingly often flag deviations as negative ones even if the project runs ahead of schedule and is under cost.

The above-mentioned common federal challenges provide better understanding and context for analyzing the challenges that faced the FDIC during the development of the ETS application. Particularly, the FDIC faced certain challenges that mainly impacted its dynamic relationship with the contractors. The agency initially used the same software contractor (vendor) which previously developed the old version of ETS (ETS-ALERT), but later reversed its decision after the inception phase. This change of contractor teams presented four challenges to the SAGE's project team members (FDIC, 2014). First, the lack of time and knowledge transfer between the original and replacement contractor teams interrupted the pace of the project development. Second, the new contractor was not fully aware of the complexity of project. Third, the agency faced some difficulties in setting up different testing environments. Fourth, the testing of ETS-SAGE revealed that the application would only function in an ideal environment but would not work in remote locations where the application is mostly needed by the FDIC examiners. These challenges caused a one-year delay in completing the ETS-SAGE project. Eventually, the agency decided to postpone the launching to 2015 until the application would be successfully functional in all testing environments.

Realized Benefits

The development of the ETS-SAGE application enabled the FDIC examiners to pull the UBPR and Call Report data from the Central Data Repository (CDR) web services in real-time. When the FDIC bank examiners used the older version of ETS (ETS-ALERT), they spent long time in manually reviewing and interpreting the changes in the Call Report information (FDIC, 2014). By the time the review process of Call Report was finished, some of the data had already become outdated for the examiners. Consequently, the delay affected the evaluation of the bank performance and the statistical/rating analysis that followed the evaluation process (FDIC, 2015). After the development of the ETS application (ETS-SAGE), the

interpretation of the data was removed and the ETS was quickly updated, which enabled the examiners to have instant access to the Call Reports and UBPR. In addition, ETS-SAGE reduced the number of systems that the FDIC examiners have to use to perform their job, which resulted in eliminating redundant data inputted in different systems. Lastly, the development of ETS contributed to enhancing security control measures for the FDIC examiners to perform their job in remote locations where they are mostly needed.

Lessons Learned

The development project of the ETS-SAGE application provides some lessons that could be of importance to other banking regulators (FDIC, 2014). These lessons include the following:

- The selection process of the software (IT) contractor was rushed, which resulted in the lack of examining other potential contractors' solutions. When the project team members reflected on their experience, they mentioned that they should have given more time to consider alternative solutions or software contractors.
- The development of an existing application (ETS-ALERT) into an enhanced version, represented by ETS-SAGE, was originally considered as an "upgrade." However, a review of the testing challenges proved that it should have been treated as a major overhaul. The RUP® framework's guidance notes require elaborate inception phase for full system development efforts. This was not the case for projects focusing on enhancement to an existing system. Therefore, a proper classification of the project scope and complexity should have been well-defined and sufficiently planned.
- The project managers should ensure that the quality of the contractors matches the complexity of the project scope. The guidelines of the inception phase in the RUP® framework indicate the importance of reviewing the availability of resources and technical experience.
- The ETS project managers stated the contractors lacked knowledge of the FDIC's technical and operational environment. The contractors did not capture the importance of the data security requirements, age of the FDIC's laptop computers, firewall limitations, and data migration technology. That lack of understanding undermined the pace of the development and caused delays during system development testing. The testing should have been performed in the FDIC's IT environment, where the FDIC examiners work in remote locations.
- The ETS project managers mentioned that the review process conducted during the Elaboration phase was stifled by the lack of constant communication. Insightful discussions and preparation with the contractors could have helped in identifying issues related to the FDIC's technical environment. Consequently, the project faced many challenges due to the contractor's lack of understanding of the ideal work environment of the FDIC bank examiners.
- The development of the ETS application was mainly driven by the quality of the testing. The testing showed the project manager where the project was headed. In addition, the testing should be performed throughout the project lifecycle and has to be done in an iterative manner. The ETS team emphasized that the quality of the testing process is a function of whether the project will meet milestones and users' expectations.
- The ETS project managers reported that the manner in which milestone reviews were conducted focused on the completing the required paperwork rather than ensuring that the goals of each RUP phase were successfully accomplished. The managers stressed the importance of discussing the project accomplishments and risks at the end of each of RUP phase. When risks were identified, elaborate plans should have been devised to mitigate these risks in a timely manner.

Practical Implications for IT Managers

The FDIC case has several implications for chief information technology officers and project managers who are responsible for developing IT projects within their organizations. The following implications could inform information managers at government agencies:

- Managers should select carefully the right information technology contractors and solution architecture. The selection is best applied during the inception phase and should take into consideration the business and technical perspectives of the project. The technical perspective should assess each proposed technical solution based on the contractor's fundamental understanding of the project's needs rather than costs.
- The scope of the project should be well-defined, assessed and agreed upon by all stakeholders (including IT managers) during the inception phase. A scoping document could be created at this phase to devise the development plan and list potential risks and milestones for review purpose. In addition, the scoping document should provide elaborate guidelines for conducting milestone reviews and assessing the availability of resources, expertise and readiness of all stakeholders before moving on to the next phase in the development plan.
- IT managers should set and define attainable milestones. Unrealistic milestones may impede the success of the project and put project members under tremendous pressure to meet the deadline (milestone). In addition, contractors may have less time to understand the complexity and scope of the project. Realistic cost plans and schedules should be devised to facilitate an informed future review of performance.
- IT managers should precaution from letting contractors steer the project. The focus should be placed primarily on the client's specific business needs. In other words, Contractors should work with the government agency to identify the best IT solution that fits the agency rather than reengineer the agency's business process to fit the proposed IT solution.
- IT implementation plans can be best supported through the inclusion of an independent risk manager such as an in-house risk/compliance manager. The independent risk management process enables the timely identification and mitigation of all potential risks within certain projects and across multiple projects. The independence factor is crucial to minimize the possibility of "pointing fingers" at the IT manager or contractor for potential project setbacks. The risk manager should also attend the meetings of the project development and develop strong knowledge of the project needs, challenges and milestones.

FUTURE RESEARCH DIRECTIONS

In the FDIC's Office of Inspector General Assessment (OIG, 2019), the agency reported that an "agile approach to regulation that can evolve with innovation," with regard to the use of emerging technology without banning or impeding their adoption. For banking processes that do not require a high degree of decentralization, technologies such as 'Distributed Ledger Technology (DLT),' could help banks improve their governance and standards around data sharing and collaboration (Csiszar, 2019). However, the FDIC does not completely share that sentiment. In fact, the agency classified the use of DLT to simplify payment system such as blockchain and Bitcoin, as potential strategic risks, which may disrupt the banking sector's payment system. In that regard, the report continues to indicate that the agency

has planned to create an Office of Innovation. The Office will be tasked with evaluating the impact of technological innovations on banks, assess potential risks and adjust its IT processes and strategies. Furthermore, the Office will share information and resources with the FDIC's Consumer Protection Division and Division of Insurance and Research. The FDIC seems to be taking slow steps towards embracing technological innovations. In May 2019, the Crypto-currency prime dealer San Francisco Open Exchange (SFOX) announced its partnership with M. Y. Safra Bank of New York to offer traders and investors deposit accounts backed by the FDIC (SFOX, 2019). The partnership allows traders to have direct access to their funds to support crypto trading. On the upside, M.Y. Bank would hold segregated accounts in customers' names to reduce counterparty risk and facilitate access to crypto market. On the downside, the FDIC's protection (losses of up to \$250,000 of customer deposits) would only cover the cash portion of a crypto transaction, not Bitcoin, ethereum, or other digital assets. The safe approach of ensuring the cash portion enables the agency to continue using its existing risk assessment tools to protect the bank customers. Future research could further examine the role of such technological advances (e.g. blockchain and crypto currency trading) and their impact on the risk assessment process at the agency and how such advances can reduce the compliance burden on regulatory agencies. In addition, future research could examine the changes that the FDIC should implement in data usage, analysis and integrity to support the use of technological innovation while maintaining a safe financial environment for the banking industry. Finally, future research could discuss the broader role of the FDIC to promote the development of blockchain and crypto currency among small banks, which have limited resources and funding to secure the safe deployment of such technologies.

CONCLUSION

In summary, as supervisory banking institutions are keen to develop their existing risk management mechanisms, the motivation for a well-executed strategy and structured development methodology become more paramount for regulators operating under strict budgets. The FDIC's ETS development experience provides insights into how bank regulators and their stakeholders can collaborate to mobilize organizational resources and use stakeholders' expertise to overcome potential challenges and execute development plans. Furthermore, the FDIC mentioned in its information technology strategic plan that it seeks to develop mobile technologies that enables authorized ETS application users to conduct their work in new ways at remote locations. To accomplish this strategic goal, the FDIC created 1,549 authorized permanent and non-permanent positions in its field workforce to conduct risk management examinations in 2018 (FDIC, 2018). The case presents further evidence on the agency's efforts to realize this goal by learning from its ETS development project. As the supervisory banking industry's reporting technologies evolve and compliance requirements increase, so do heightened risks that might affect the outcome of the FDIC's risk management process. In this chapter, the FDIC's development work with the ETS should inspire the agency to continue its on-going efforts to provide secure quality data and effective risk assessment procedures. Moving forward, the FDIC's newly created Office of Innovation puts the agency at a leading position to assess the potential of technological advances such as blockchain, artificial intelligence and crypto-currencies. Many bank executives and regulators still associate technologies such as blockchain to wild fluctuations in crypto-currency values. Therefore, the agency has to consider carefully the viability and challenges of such technologies to facilitate banking operations while maintaining a safe regulatory environment.

KEY TERMS AND DEFINITIONS

Agile: A group of software development methods based on iterative and incremental development, where requirements and solutions are created through collaboration of cross-functional teams.

Examination Tool Suite (ETS): It is a primary examination tool used by the FDIC's Division of Risk Management Supervision to produce the FDIC's Report of Examination.

Federal Deposit Insurance Corporation (FDIC): It is an independent government agency of the U.S. government that protects customer's deposits in insured banks and depository institutions.

Federal Financial Institutions Examination Council (FFIEC): It is a formal inter-agency government body that create principles, standards and report forms for the federal examination of financial institutions by the Board of Governors of the Federal Reserve System, the Federal Deposit Insurance Corporation, the National Credit Union Administration, the Office of the Comptroller of the Currency and the Consumer Financial Protection Bureau.

Rational Unified Process (RUP): A comprehensive and standard process framework that provides best practices for software implementation and development to support project management.

Stakeholder: A representative group of people and organizations that share a common interest in the organization. In the FDIC context, stakeholders include clients, employees, vendors, banks, and regulators.

System Development Life Cycle (SDLC): A comprehensive iterative methodology that drives the implementation of new systems through planning, requirement analysis, designing, building, implementing, testing and maintenance.

ENDNOTES

¹ <https://www.fdic.gov/regulations/resources/call/call.html>

² Interagency Exam Repository is a system that routes and stores electronic copies of the FDIC's Report of Examination.

³ GENESYS stands for General Examination System, which is an application that summarizes and communicates examination findings to a bank's Board of Directors.

Artificial Intelligence as an Enabler for Developing Business Systems

3

N. Raghavendra Rao

FINAIT Consultancy Services, India

INTRODUCTION

Decision making in any business is considered to be a primary activity. All managerial activities revolve around decision making. Business executives in enterprises are the decision makers. Enterprises have executives at the various levels in their organizations. Some of them are assigned the task of taking decisions in their functional areas. Executives at the senior management level will take the responsibility of taking decisions for the various business activities. Their decisions are considered to be policy making decisions. Their policy decisions will be in the areas such as Capital investment purchases, setting targets for production and marketing of their products. Their other policy decisions will be related to other important activities and functional areas related to their business. Effective information systems in an enterprise will facilitate the executives in taking decision. Over a period many new concepts have emerged in the discipline of information and communication technology. These concepts have provided a scope for designing and developing a business model to suit the business needs of an enterprise. One of the concepts that recently emerged is artificial intelligence. It is gaining importance in the present business scenario for multiple reasons. One of the reasons is the severe competition in the global market. This chapter mainly talks about the importance of the concept of artificial intelligence in designing and developing decision support systems for the enterprises.

Background

In earlier years the process of decision making was considered to be an art and a special talent. This talent was acquired by executives over a period through their experience. It was an art because a variety of individual styles could be used in approach and solving the same types of issues or problems related to a business. Their styles have been based on creativity, judgement, intuition, and experience. Their approach is not the basis of systematic quantitative methods (Efraim Turban, Jay E Aronson, and Ting-Peng Lang, 2006). In the present business scenario, business and its environment are becoming more complex day by day. Business executives need to equip themselves and keep changing in their approach for taking decisions in the present changing scenario.

Changes in Decision Making Process

The process of making a decision has become more complicated and difficult. This is because of several reasons. First reason, there are several alternatives available much more than earlier days. The advancements in the discipline of information and communication technology have also created many alternatives for decision making process. The second reason is the cost of making errors can be large because of the complexity and magnitude of business operations. Continuous rapid changes in business

DOI: 10.4018/978-1-7998-3473-1.ch032

environments are forcing the business executives to change the method of decision-making process. This can be considered as a third reason. Finally responding quickly to the changes in the market is forcing the business executives to change their decision-making process (Efraim Turban, Jay E Aronson, and Ting-Peng Liang, 2006).

Decision Support Systems in Enterprises

Management information systems facilitate business executives to take a decision in the areas of budgets, financial analysis, and business forecasting. The process of taking decisions in this area is generally considered to be as a structured approach. The category of semi structured decision process covers such as production scheduling, inventory management, new product designs and quality assurance. Ready-made software packages related to customer relationship management, supply chain management, and knowledge management are available in the market. These software packages facilitate the decision process in the above areas. The decisions pertaining to investment in acquiring hardware and software, new technology, planning in research and development can be considered as an unstructured decision process. Software related to knowledge management system, expert system, and enterprise resource system is generally developed within one's organization for taking business decisions. This is because of the sensitivity of the data for taking decisions in an enterprise (Janakiraman V S, Sarukesi K, & Gopalkrishnan P, 2017)

Concept of Decision Support Systems

Decision support systems are designed and developed by the combination of the intellectual resources of individuals and the concepts of information and communication technology. These decision support systems facilitate in improving the quality of decisions taken by the executives. It is interesting to note that many decision support systems are the result of making use the concepts emerged in the discipline of information and communication technology over a period. In the case of supply chain management, the stakeholders are vendors of components, production department in an enterprise, and the customers of the enterprise's products. The software is developed based on the interactions of the stakeholders of the supply chain management. The knowledge management systems are the result of the participation of the employees of an enterprise by sharing their knowledge and experience. It may be noted that the role of the stakeholders is important in creating a decision support system for an enterprise. In the present business scenario, the concept of artificial intelligence is gaining importance for designing and developing decision support systems for an enterprise.

Technology Trends

Several technologies in the discipline of information and communication technology directly and indirectly play an important role in decision support systems. Many new technologies have been around for decades. These technologies have become feasible after the easy availability of inter connectivity between the computer systems (Khanna V K, 2004).

Evolution of Artificial Intelligence

The development of artificial intelligence has mainly four stages. First in the year 1956 a group computer scientist at Dartmouth college have discussed the great potential of computer applications. They were

confident that when the computer systems were provided enormous computing power, would be able to solve many complex problems and outperform human beings in many areas. At that time, scientists had little understanding of the complexity in human intelligence. They were only optimistic about what the computer could achieve. Many solutions created at that time were primitive. Hence this stage can be called native solutions stage.

After several years of trial and error, scientists started focusing on the development of more effective problem-solving methods such as knowledge representation schemas, reasoning strategies and effective search heuristics. The approach followed at this stage was the development of general- purpose methods software packages. This stage can be termed as the general method stage.

After developing enough general methods, software the application software related to real world purposes has started gaining momentum in the business world. The application at this stage was different from the earlier stages. Solving common sense problems is difficult. Therefore, most applications have been targeted at narrowly defined domain and with specialized knowledge systems of this kind are called expert systems. The feature is that acquisition of expert knowledge plays a key role in the development of such systems. This stage can be said as domain knowledge stage.

Since 1990 more advanced problem-solving methods have been developed. It has become a strong need to integrate multiple techniques and solve problems in multiple domains. Hybrid computer systems such as integrating rule based and case-based systems or integrating artificial neural networks have started becoming popular in the business world (Robert J Schalkoff, 2011). It has become necessary to make use of genetic algorithms. This stage can be termed as the integration stage. The use of artificial intelligence in decision support system is the result of integration stage.

Concept of Artificial Intelligence

The artificial intelligence is an area of computer science. The artificial intelligence has two basic elements. First, it involves understanding the thought processes in the human mind. Second, it deals with the replication of these processes in computer systems. If a computer system performs a particular act in a similar way or equivalent to the behavior of a human being, it can be considered as an artificial intelligence. A human being is an intelligent based on the following abilities (Ayaz Ahmad, 2012).

- 1-Learning or understanding a situation from one's experience
- 2-Making sense out of ambiguous or contradictory statements
- 3-Responding quickly and successfully to a new situation
- 4-Aplying reasons in solving problems or handling a situation with a clear mind
- 5-Applying rational approach in a perplexing situation
- 6-Applying one's knowledge in evaluating the various options available for solving an issue

Difference Between Artificial Intelligence and Human Intelligence

Both types of intelligence have its own advantages and disadvantages.

The following comparison gives the potential value of the above two intelligences (Rajendra Akerkar, 2014).

- 1-Artificial intelligence is permanent as long the computer systems and programs are not changed. Human intelligence is not dependable from the enterprise's perspective.

It is because executives can change of employment. Other executives in the organization may not be aware the approach followed by the executive who has left the organization.

- 2-Transforming knowledge from one person to another person usually requires a lengthy process. Expertise can seldom be duplicated completely. However, knowledge stored in a computer system can be easily transformed from one computer to any other computer system.
- 3-There are many instances in which computer systems cost is less expensive when compared to hiring professionals. This is especially true when knowledge is disseminated over the computer systems.
- 4-Artificial intelligence in a computer system is consistent. Generally, people are erratic. They do not always perform consistently.
- 5-Decisions made under artificial intelligence process in a computer system can be easily documented. On a later date it is possible to trace the decision process in the computer system. In the case of human intelligence, a person who has taken decision may not be able to recall the reasoning process and assumptions made while making the decision.
- 6- Artificial intelligence in a computer system executes certain tasks much better and faster than human beings.

Unique Ability of Human Beings

Acquiring knowledge is inherent in human beings. In the case of knowledge in the computer systems requires carefully designed and developed. It may be said that Artificial is a tailored knowledge (Elaine Rich, Kevin Knight, & Shivashankar B Nair, 2014).

Cognitive Limits

The term cognitive limits indicate that an individual's problem-solving capability is limited when a wide range of diverse information and knowledge is required. A group of professionals with diverse knowledge is required to handle the issues or problems. There may be issues related to coordination and communication in some groups. In such cases arriving at a decision will pose a problem. Computer systems facilitate executives in enterprises to get access to the vast stored information in the computer systems for processing (Dan W Patterson, 2017).

Characteristics of Human Beings

Sensing, reasoning, and action are the three main characteristics of human beings. Sensing helps individuals to identify the problems. Reasoning facilitates individuals in selecting one of the alternatives available for arriving at the decision process. Once the alternative is selected, the individual can act on his/her decision. The above three characteristics are required to be embedded in a computer system for creating artificial intelligence in a system (Kavitha S & Balasubramanian, 2012).

Sensors

Sensors are used for image processing and speech recognition in computer systems. The image processing sensor recognizes the important

Faces, objects, and other related business tags and devices.

Sensors can be human sensations.

Reasoning

Reasoning in the computer systems is generally related to language processing, assessment of a situation, logic and evidence- based interface.

Action

Sensors and reasoning in computer systems facilitate for taking decisions by executives in the business enterprises.

Machine Learning

Human learning is a combination of many complicated cognitive processes, including induction, deduction, analogy and other special procedures for observing and analyzing examples. Machine learning techniques are no different. Most of the professionals adopt similar ideas and have them implemented in the computer systems for artificial intelligence. There are many methods followed in machine learning technique for artificial intelligence (Vinod Chandran S, & Anand Hareendran S, 2014).

Machine Learning Process

While creating a business model under the artificial intelligence concept, the following steps need to be followed (George F Luger, 2009).

Identification of Data

Identifying the relevant data sources is the first important test.

Improving the target data in the relevant data sources needs to be carefully handled, while developing machine learning algorithms.

Preparation of Data

The relevant data identified for the specific model should be secured and clean. This facilitates to create a good machine learning application

Selection of Machine Learning Algorithm

There are many machine learning algorithms available in the market. One must select the appropriate machine algorithm on the basis of the business needs of an enterprise.

Creation of a Business Model

One must apply the algorithm depending on the type of data chosen for a particular type of business application. It will be better to test the model as many times as possible before the model is implemented.

Business Forecast

Machine learning algorithms are applied to analyze on the vast data for business forecast.

Assessment of the Business Forecast

One must assess the outcome of the business forecast. This assessment will help the executives in enterprises either to accept the business model or they can suggest for an improvement.

Team Members in Machine Learning Process

Machine learning is a joint effort of the various specialists. A team consists of data scientists, data engineers, business analysts, domain and functional experts to collaborate the task. This team must focus on the business problems and business issues (Sharma D P & Sweta Sharma, 2013).

Machine learning is a main element in artificial intelligence. This learning process enables a computer system to learn from the data. This is not through the conventional explicit programming. Significance of algorithms is a set of instructions for a computer in interacting with the data for manipulation and transforming data (Eugene Charniak, & Drew McDermott, 2006).

Knowledge Harvesting and Intellectual Capital

It is required that the team members should be familiar with the concepts such as knowledge harvesting and intellectual capital while developing decision support systems under the artificial intelligence environment. These concepts are briefly explained below.

Knowledge Harvesting

In agriculture the cultivable land is made use of growing a crop. Depending on the season a particular type of crop is grown on the same land.

The manure is used to increase the output of the crop of the cultivable land remains same. The agricultural output from the same land depends on the season and the type of manure used.

Similarly, the knowledge harvesting system is similar to the agricultural land in an organization. Data and the information from the knowledge management are made use by an employee depending on his/her wisdom. This approach is known as the knowledge harvesting initiative. The method followed by an employee inferring and interpreting the information varies depending on his/her experience and business knowledge. This can be compared to using different type of manure for the different type of crop output from the cultivable land.

Information is the main base in the knowledge harvesting system. Cultivable land is the main base in agricultural harvesting. Knowledge and wisdom are the important elements in the knowledge harvesting system. They can be considered to be equivalent to the manure. Manure and the latest cultivation

Manure and the latest cultivation techniques play an important role in the agricultural harvesting (Rezgui & Miles, 2011).

Intellectual Capital

Intellectual capital is the creation of more wealth by the dint of knowledge. The cycle of intellectual capital begins at an inner faculty of a human being such as application of skills, knowledge, experimentation and research. These elements lead in the process of creating the intellectual assets. Thus, it begins at the knowledge level and ends at the creation of intellectual capital.

Knowledge is more valuable and more powerful than natural resources. In the present environment of shortened business cycles and rapid technological change, the intellectual framework represents the primary value creation dynamics of the firms. Now the term intellectual capital has different connotations and is very often synonymous with intellectual property, intellectual assets, and knowledge assets.

There are mainly four components in the intellectual capital. They are human capital, structural capital, business assets, and intellectual property.

Human Capital

It relates to a firm's human resources, including knowledge and know how that can be converted to value. This is said to reside in people, organizational routines and procedures.

Structural Capital

It relates to the firms supporting infrastructure.

This includes both physical infrastructure such as buildings, computer systems, other related assets and intangible structure such as history, culture and management.

Business Assets

Business assets are defined as the structural capital a firm uses to create value in its commercial process such as processing facilities, and distribution network.

Intellectual Property

It relates to the intellectual assets of the firm for which legal protection is obtained. It includes patterns, trademarks, copyrights, trade secrets, technology, and digital information.

Case Illustration

The following case illustration gives an idea in making use of the concept of artificial intelligence in a textile mill in India.

Coimbatore is a textile town in South India. This town is known as Manchester of South India. There are many textile units in this town producing yarn, cloth, and dress materials. The first generation of people in this town has either started their units after getting formal training or inherited the textile units. Most of them have basic education only. They have started their units with a small capital. Most of the units were established in the middle of the last century. It was because of the favorable market conditions; many units made profits and expanded their business activities. Most of the units have created a brand image for their textile products. The people who start a textile unit is known as a mill owner. Even

though many of them have more than one textile unit, still they are known as mill owners. Generally, they are never referred as industrialists.

3 G textile mill was started in mid 1950's by a textile mill owner. He has rich experience and good knowledge about the textile business. He has a basic schooling only. His interest and passion for textile business has helped him to create a name for his textile products. He has trained a group of employees for his business. They are loyal to him. They take pride being associated with him for a long period of time. Most of them have either formal or no basic education. The mill owner alone thinks of business strategies. He never involves the group trained by him for designing business strategies. He expects them to carry out his instructions only.

Mill Owner's Method of Working

Cotton is very important raw material for manufacturing yarn. Cloth material is manufactured on the quality of yarn used. Selection of cotton mix is an important element to produce yarn. He updates himself with the latest information pertaining to the technical aspects and markets for his textile business. He is confident of himself because of his rich experience in the technical process of manufacturing yarn and cloth material.

The mill owner has identified a large room in his mill premises for selecting cotton to produce yarn. Samples of cotton are brought by the different cotton merchants and kept on a big table in the room. Brief details of sample cotton are kept along with it. The details mostly cover the information pertaining to the year of production name of the country type of cotton has been grown along with the rate of cotton per bale. The mill owner makes use of his both hands for testing the strength of the cotton. He is able to select the cotton from his manual method. He does not believe in using any equipment for testing and selecting the cotton for production of yarn. Further, he decides the mix of cotton from his experience. His decision is based on the percentage of imported cotton to be mixed with the cotton produced in India. While mentally he thinks of the mixture of the different variety of cotton and he visualizes the color of dyes to be used. He also works out mentally the cost of yarn per spindle. He also decides the price at which the yarn is to be sold. While deciding the type of cloth is to be produced, he keeps in mind the prospective customers' tastes and trends in the market. He also interacts with the suppliers and makes inquiries of the welfare of their families. He feels that this interaction with them is required for maintaining a good relationship with the suppliers. Later he gives instructions to his supporting staff for placing the orders. He has been following the above procedure from the day he started his business activities.

The next generation of his family is not interested in the management of the mills. They prefer to pursue their own professional interests. He has not forced his **sons** to take over the management of the mills. He has realized that he did not make efforts to create interest among his sons in the textile business. Further, he felt bad that he did not give the opportunities to his loyal staff for involving the decision process. He did not encourage them to express their views and strategic planning for the business. He decided to share his concerns with his granddaughter Ahalya who has got a master's degree in computer science. Ahalya felt it would be advisable to help her grandfather in the business. She started going along with her grandfather to their textile mill daily. She observed that her grandfather is involved in every activity in the mills. Everyone takes instructions from him. Some of them are not clear about technical and business process.

Ahalya felt that identifying the right type of people and forming a team within in their organization acquiring the knowledge from her grandfather will be a difficult proposition. One interesting aspect is her grandfather mainly depends making use of the information from his memory.

She felt making use of the concept of artificial intelligence for taking care of the process followed by her grandfather will be the best solution.

Ahalya has expressed to her grandfather that she would make use of the concept of artificial intelligence to capture his knowledge for the posterity.

Grandfather has felt happy that her granddaughter has taken initiative to create a system to guide the employees in his organization. He explained every aspect of the business. He also explained how he makes use of his knowledge and experience in the areas of production of textile products, marketing, pricing and costing. Based on the inputs provided by her grandfather, she created a database. This database mainly contains the procedures and business processes followed by him.

This database is mainly for her to know the various aspects of the textile business

Artificial Intelligence and Machine Learning for their Textile Business:

Ahalya herself been an information technology professional, she has recruited a group of software professionals who have experience in making use of the concepts such as artificial intelligence and machine learning for their textile business. Ahalya explained in detail the process followed by her grandfather. After analyzing the procedures, she along with the new team of software professionals designed another database with different modules. Various modules contain all the required information relating to cotton, supplier, types of dyes, tastes of customers, market trends, and costing. This database provides the selection process of cotton, color combination of dyes. Production planning details of yarn and cloth are also stored. This database is known as textile knowledge-based system.

Machine Learning Algorithm

The group has allocated themselves the task of writing machine learning algorithms the various processes and activities in the textile mill. One of their algorithms suggests the mix of cotton. On the basis the suggestions from the machine learning algorithm, the strength of the cotton is physically tested in the quality testing laboratory. Once the favorable report is received from the quality testing laboratory. The machine learning algorithms will suggest the mix of dyes, on the basis the tastes of the customers in the various parts of India and other countries across the globe. The team has trained the computer system through machine learning algorithms to suggest various aspects

Of designs, color combination to produce the cloth material. The team has introduced many new aspects in the textile business through machine learning algorithms. Ahalya is thrilled to know that her grandfather is happy with the outcome of her initiative with the concept of artificial intelligence.

She has organized for the orientation course in the area of artificial intelligence for their employees who have evinced in making use their textile artificial intelligence system. She has encouraged them to provide

Their ideas for fine tuning their artificial intelligence system. They are also given an opportunity to think differently. They can also suggest changes in the business process of their textile business.

Discussion

Ahalya has started recruiting young talents with experience to assist her in the business activities. She encourages every member of her team to make use of artificial intelligence system created by her team. She has weekly meetings with them. She is open to the suggestions from them. In one of the meetings a group of young executives who joined the textile mill recently, have expressed to suggest an innovative way for designing textile products. They have indicated that the textile mill is not making use of multi-

media concepts in the design of a cloth and dress material. They are given freedom to design the textile mill products with their ideas. They have designed samples with the various color combinations with multimedia concepts. They have invited selected priority customers to their office during the office hours to view the design on the computer screen at their office. Some of the customers have expressed their views and gave suggestions to the design shown to them. The executives have taken note of their views and suggestions. The inputs are discussed with Ahalya. After analyzing the inputs, they have decided to carry out the changes wherever are feasible. These interactions helped them to know the latest tastes of the group of customers. This helped them to redesign their products. The Sale of their products is likely to increase. An open innovation initiative with the artificial intelligence system approach by the young executives has widened their knowledge in designing the textile products for the needs of the market (Stuart J Russell & Peter Norvig, 2007).

Observation

A mill owner with having a rich knowledge and experience in the field of textile business could not find the next generation in his family to the management responsibility of his textile mill. His knowledge and experience have not been documented. His granddaughter Ahalya who belongs to the third generation in his family has taken the initiative in making use of the concept of artificial intelligence in creating an information system for their textile mill (Oguz F & Sengtin, 2011). Her interaction with her grandfather and her interests in the textile business has enabled her to store his knowledge and experience in the information system. This information system is mainly created for making use of machine learning algorithms to facilitate creating a decision making system for their executives in their organization. This information system developed under the artificial intelligence environment has helped the young executives in her team to think differently. Their initiative has also resulted in an open innovative approach in designing and marketing of their textile products.

Future Directions

Shortened business cycles and rapid technological changes are forcing business enterprises to adopt the concept of artificial intelligence for facing new realities in the present business world. Some studies have indicated that only a small portion of the corporate knowledge is in the shareable form. The majority is in their employees' brains and it is not in a shareable form. Business enterprises should make use of the human centered assets in their organization for creating an artificial intelligence environment in their organizations. There is a good scope for developing a decision-making process system with the machine learning algorithm in the artificial intelligence environment (Judith Hurwitz, & Daniel Kirsch, 2018).

CONCLUSION

There are many structured and unstructured data are available in the present business world. Most of the structured data is created in a particular format. Unstructured data do not follow a specified format. Unstructured data is still widely underutilized by business enterprises. The unstructured data are mainly provided by social media sites. The concept of artificial intelligence plays an important role in handling structured and unstructured data for decision making process for business enterprises (Kristian Hammod, 2015).

INTRODUCTION

Knowledge management (KM) is a term that has existed since the 1980s and can be defined as a systematic and intentional creation, updating and using knowledge to maximise the efficiency of an organisation (SlavĀcek, 2011) generating a common language and improving communication across it (Nadarajah and Latifah, 2016). This topic has received particular attention because it offers a means for organisations to develop competitive advantages (Wang & Yang, 2016). Among other issues, questions related to individual knowledge and its externalisation or formalisation, or the dissemination of knowledge in organisations has been deeply investigated (Kalpic & Bernus, 2006).

Organisations concerned with knowledge management focus on creating organisational knowledge to achieve efficiency, generate innovative products and improve customer service (Birasnav & Rangnekar, 2010). These organisations, upon making better success, come to realise the importance of knowledge as a resource that generates organisational benefits (Bitkowska, 2016). On the other hand, business processes are a fundamental part of daily work in organisations (Giacosa, Mazzoleni, & Usai, 2018). Business Process Management (BPM) is considered an important area of organisational design and a recognised source of business performance. At the same time, BPM research has paid a lot of attention to the development capacity of process management in organisations (Lehnert, Linhart & R  glinger, 2016). Currently, BPM has reached a certain maturity. This is justified in the amount of literature about it and, the existence of specialised journals, for example, The Business Process Management Journal and conferences, for example, The BPM-Conference in the seventh year, as well as the institutionalisation of specialised BPM degree programs in several universities, show that it is not a temporary fashion but an orientation encompassed in the science of management (Houy, Fettke Loos, 2010).

Since the 1980s, the management of business processes has been an intensely discussed topic in the field of information systems research (Houy et al., 2010). In previous decades, many organisations have embraced technological initiatives that allowed them to make changes, manage their businesses and improve their performance (Harmon, 2010). These initiatives had been extended through departmental and organisational boundaries, including clients and suppliers, resulting in a transformation of functional organisations into process-led organisations. The latest phenomenon in flexible technologies to changes

DOI: 10.4018/978-1-7998-3473-1.ch033

in market trends are known as BPMS (Wong, 2013). BPMS represent a type of software that allows the promulgation and management of business processes of an organisation (Aalst et al., 2003), through the design and modelling of these processes (Smith & Fingar, 2003). Thus, BPMS paved way for the faster adaptation of organisations to continuous changes in the market and its consumers. Companies, that adopt this technology, are interested in the value that these systems generate through the continuous improvement of business processes. This enables them to position themselves at the forefront of a competitive market (Wong, 2013).

Wu, Kao & Chen (2015) indicate that knowledge creation is strongly linked, among other aspects, to processes. Based on this, it is implied that, if the knowledge of an organisation is used and linked to the processes, BPMS play an important role in knowledge management when these processes are automated through this technology. In this way, process management and knowledge management are two interconnected paradigms that can generate synergies, for example, the speed and agility with which knowledge can be managed and standardised once BPMS is incorporated in a company. The main objective of this article is to present a transition analysis, through previous literature, knowledge management, process management and automation, as well as the possible relationship between knowledge management and BPMS.

BACKGROUND

In modern times, the competitiveness of organisations is derived mainly from intangibles instead of tangible resources (Matayong & Mahmood, 2013). The intellectual capacity of individuals, that is, their knowledge, is considered an intangible resource possessed by the organisation in which these people work (Šajeva, 2010; Van Looy & Van den Bergh, 2018). In general, knowledge resides in the minds of people and organisations have to ensure their availability whenever necessary (Tseng, 2008). Knowledge is considered such a valuable resource for an organisation that it is very important to manage it, in the same way, that any other business resource, whether human or capital, is managed. At present, it is perceived as a strategic resource within the company, therefore, it should be subject to constant identification, measurement, acquisition, development, utilisation and protection (Bitkowska, 2015). Thus, in the era of the knowledge economy, organisations have a great interest in managing such knowledge (Wang & Yang, 2016). The term “Knowledge Management” is seen as an organisational activity that leads to success and is a stimulus for debate, since it is subject to a wide range of interpretations (Rechberg & Syed, 2014). This discipline, in organisations, evolved around the need to increase sales, improve work practices and make decisions, as well as shorten development time, improve customer service, train employees and innovate (Dotsika & Patrick, 2013). Knowledge Management (KM) provides efficient procedures which enhance value creation in organisations (Šajeva, 2010). As knowledge is the central element of this management, the competitiveness of organisations will depend on how they are applied, exploited and integrated into them (Alavi & Leidner, 2001, Šajeva, 2010). KM refers to a deliberate and systematic approach to ensure the full utilisation of the base knowledge of an organisation (Han & Park, 2009).

Knowledge management is creating a growing concern in the field of management research and practice (Giacosa et al., 2018). It develops a very important role in the innovation capacities of a company and also improves the quality of the working life of the workers (Wang & Yang, 2016). In contemporary companies, observation has shown a decrease in the interest for assets, such as inventory or capital, and an increase in the importance of non-material assets, such as skills or professionalism, which are

constituted by knowledge. The management of knowledge in a company determines the value of the organisation as a whole and not only its material assets (Bitkowska, 2016).

In another sense, it is necessary to refer to the systems used in knowledge management in an organisation. These systems will serve to capture the knowledge, as well as store and distribute it. These systems could be technological, performing the previously mentioned activities in an automated way. In this perspective, the use of technology for the automation of processes can be framed in specific reference to the BPMS. Hansen, Nohria & Tierney (1999) suggested that if the task can be routinely and easily standardised, technical solutions are appropriate for knowledge management, but if they cannot, then human relationships are preferable. Referring to the technical solutions that can automate knowledge management, it should be noted that substantial investments in technology and infrastructure do not always guarantee the success of knowledge management. Rather, it is with the commitment and willingness of employees to participate in initiatives that achievements are made (Lin, 2011).

Nowadays, information technologies have become relevant for business management, being a verifiable reality that its application is drastically changing the manner of competition between companies and what they demand from professionals (Polakovic, Šilerová, Hennyeyová, & Slovákova, 2018). However, although companies are aware of the important role that technology plays in their information systems, it does not imply that they will incorporate them into their business processes (Arjonilla Domínguez & Medina Garrido, 2009, p.37). On the other hand, information and communications technologies (ICTs) by themselves do not make business management efficient as organisations need other resources, such as human resources or management skills (Powell & Dent-Micallef, 1997). A true balance between technology and process is necessary, otherwise, users and administrators can bypass information systems (Bendoly & Cotteleer, 2008). Jackson & Sloane (2007) remarked that technological development offers consistent improvements to business processes. In this way, an organisation can improve the efficiency and effectiveness of its business processes, develop new processes or generate re-engineering processes. These new processes will increase in value when designed and disseminated through the BPMS, which will execute and monitor these processes (Hammer & Champi, 1993). Information technologies support the management of business processes and involve changes in: (1) The organisation (in the corporate culture, the form of leadership, etc.), (2) The Processes (service support, service provided, etc.) and, (3) In the technology itself (application integration, analysis, visualisation, automation, etc.) (Climent, Mula & Hernández, 2009).

In the past decades, many organisations have sought to embrace technological initiatives for change and thus, manage their business processes with the intention of improving their performance (Harmon, 2010). These technologies have extended along functional and organisational boundaries to include clients and suppliers, resulting in the transformation of an organisation by functions into an organisation by processes (Polakovič et al., 2018). However, the existing technology was not flexible to adapt to new needs, but thanks to the BPMS, the processes became more executable, and work can be automated without the need for programming. This allows the systems to adapt to the company and not the other way around. Hence, the business process is released from its mould. And it is through an agile process management that the entire value chain can be monitored, improved and continuously optimised (Smith, Fingar & Scott, 2002). BPMS make processes operative, making explicit designs of them (Weske, Van der Aalst & Verbeek, 2004). Shaw, Holland, Kawalek, Snowden & Warboys (2007) determine that the BPMS seek to improve the efficiency, effectiveness and governability of business processes. The importance is such that, for example, the company Gartner, in the year 2008, had its BPMS among the third of the top 10 strategic technologies¹.

It is also noteworthy that, at a professional level, there is much confusion with the term BPM (Business Process Management). It is thought that by acquiring the technology the processes can be automated, solve the problems of coordination and improved efficiency will come automatically (Polakovič et al., 2018). Nothing is further from the reality. The acquired technology is nothing more than a software that does not include techniques, methods, or knowledge about how it is better to design the processes. Technology is only a tool that supports the business processes already implemented in an organisation (Laurentiis & Robledo, 2011) and its subsequent modifications, as prescribed by those responsible for designing or redesigning the processes. In other words, BPMS are tools that provide companies with the ability to model, execute, monitor and analyse business processes. Process modelling is used to get the graphical representation of a current or future process within the organisation². Business analysis is a prerequisite for the design and development of information systems, as it can reduce the number of problems caused by misunderstandings between people who belong to the business area and those of Information technology (Bernardino Araújo, Rodrigues Filho & Franco Gonçalves, 2016). These systems are not intended to replace existing applications within the organisation. The idea is to add the use of these applications to a new process and use their information, being able to integrate all that information in a more flexible and adaptable way than if the software should be reprogrammed (as it does with the workflows), this way businesses become more agile (Wong, 2013). This makes it much easier to integrate with other heterogeneous systems and normally, serves as a platform for the development of process-based applications (Rhee, Bae, & Choi, 2007; Smith & Fingar, 2003).

As just mentioned, one of the most attractive features of BPMS technology is flexibility. This is because it uses a process modelling system and not programming. This modelling system allows the owner of the process to be able to redesign it graphically whenever necessary, without resorting to programming. Another interesting feature is that BPMS provides the ability to coordinate activities across multiple applications and not replace existing systems, but integrate people and available applications and make the processes work at the service of the organisation at all times (Arjonilla & Medina, 2009, p.128). In this sense, companies pay a lot of attention to the efficiency of BPM, due to the high number of processes they can manage. The more business processes are controlled by this tool, the more efficient these processes will be (Rhee, Cho, & Bae, 2010). Today, the market requires a quick response to customers. To react quickly a company has to perform better in its business, and the efficiency in the execution time of its processes is one of the objectives to achieve (Rhee et al., 2010). The analysis of the academic literature on BPMS reveals two different perspectives in its scientific treatment, Houy et al. (2010): The management perspective and the technological perspective. In this sense, there are two important paradigms in the field of information systems that can be matched with each of these perspectives: (1) “Science of behaviour” and (2) “Science of design”. The first seeks to develop and justify theories in the context of the analysis, implementation, management and use of information systems. In contrast, the design paradigm focuses on innovation, design and use of technological devices. Therefore, the academic papers on BPMS can be grouped into those that give greater importance to the technological component, that is, to design, and those that try to analyse BPM as an administrative theory (Houy et al., 2010; Poelmans, Reijers & Recker, 2013; Rhee et al., 2010). The present work, as has been observed, is framed in the second perspective, that is, analysing BPMS from a managerial, administrative or management point of view.

On many occasions, BPM systems have been considered as just another application software, although based on the above, it is not surprising that there are those who understand them as the basis of a new paradigm (Ravesteyn, 2007). It is wrong for companies to believe that the adoption of BPMS will mean the automatic achievement of their operational and strategic objectives. Even the best BPMS technol-

ogy will not be able to offer answers on how to design and manage the processes better, this will always be the responsibility of the administration of each organisation. Nevertheless, BPMS can contribute to this, helping in the execution of the strategic planning of the organisation, allowing a better adaptation between the strategy and the business processes of the company (Trkman, 2010).

BPMS TRENDS

Certainly, the future is unpredictable; however, it is possible to set trends based on information and knowledge of this subject. First of all, companies seek to gain in simplicity, they want to reduce their methods and use processes that are easy to create and modify according to their needs. In short, they seek to reduce dependence on rigid technologies and appreciate the advantages of BPMS in this regard. Second, companies seek to anticipate and predict results, which can be obtained from data analysis. Being able to control operations and predict or prepare is a great advantage. In this sense, the flexibility of the BPMS allows organizations to be more agile and efficient to achieve these ends. And thirdly, the BPMS allows raising the level of collaboration which will improve the productivity of the organization, as well as increase the level of commitment among the employees (Paschek, Ivascu, & Draghici, 2018).

On the other hand, there are other issues that BPMS can support: (1) the shift from business processes to customer-focused processes, which expands processes beyond the boundaries of the organization, (2) mass-produced processes are replaced by more individualized processes, (3) processes will be digitized and will not require human intervention, or in any case human, machines and things will coexist, giving rise to new processes, (4) anticipating the client's needs, even before he interacts with the process, being open to share private data and, (5) based on experimentation, it is all about learning from customers as soon as possible, with prototypes or other versions of the process (Paschek et al., 2018).

Digital transformation (DT) is also a trend in which BPMS have a place. DT is an organizational issue, in which people creatively use new technologies to change how they do their work, making new business models available. Those who create new models have the advantage of using the process or business in their behalf. In this way, firstly digital transformation takes place and, secondly, it emerges as a new opportunity for BPM to achieve the promised results and change the business as we know it (Pihir, 2019). Following this idea, some researchers try to integrate the technologies with other paradigms, such as KM. Thus, an important future trend is to complete processes with systems capable of containing information or knowledge (Żytniewski, 2018). In this context, BPMS are systems capable of boosting the impact of KM within organizations, due to their flexibility, their integration with other tools and their capacity to disseminate information.

KNOWLEDGE MANAGEMENT AND BUSINESS PROCESS MANAGEMENT

The management of business processes and knowledge management have been widely developed as autonomous disciplines. However, for an organisation that considers both issues, both must be managed in a coordinated manner (Slavicek, 2011). Organisational knowledge represents the intellectual capital that must be captured by the organisation to incorporate its value into business, thus, knowledge becomes a resource that creates value for the company (Rastogi, 2002). The knowledge that is in a person's mind is limited in value but that value can be increased exponentially when redirected, reused, and integrated into business processes (Douglas, 2002). In the 1990s, companies became aware of the risk of losing

key knowledge belonging to their organisations, which is often present in the heads of their employees (knowledge that is not explicit and is not available for the use of other individuals). At the same time, the demand for faster growth of knowledge and skills of employees has become a new point of reference for managing organisational knowledge (Kalpic & Bernus, 2006). Increasingly, organisations are looking for possible ways to make their processes include the necessary knowledge and thus, be able to compete better in their markets (Marjanovic & Freeze, 2012).

Process management and knowledge management are intimately connected and synergistically inter-related. In this sense, elements of process management, such as the result of organisational learning in the execution of processes (learning by doing), the re-engineering of business processes, the modelling of business processes and the management of the quality of the processes can be used for exhaustive knowledge management and the construction of knowledge bases in companies (Kalpic & Bernus, 2006). Kalpic & Bernus (2006) believe that a BPMS, specifically designed for the efficient management of processes, is also an important tool for knowledge management that allows the transformation of informal knowledge into formal knowledge and facilitates its externalisation, distribution and subsequent internalisation. Also, it is logical since those users of a BPMS who generate knowledge in their daily tasks will probably incorporate the knowledge generated into the processes and the BPMS itself. Uncoded knowledge is slow and expensive to transmit. Ambiguities abound and can only be overcome when communication is face to face, so the errors of interpretation can be corrected by the use of immediate feedback. On the other hand, the transmission of encoded knowledge does not require the contact of individuals and can be carried out through impersonal means. Messages are better structured and less ambiguous if transferred in encrypted form. This is precisely what happens when organisational knowledge is integrated into a BPMS because that knowledge indicates the best way to perform a process (Lehnert, Linhart and Roeglinger, 2017). Thus, the executors of the processes put into practice the knowledge that has been codified in the BPMS that manages the operation of this process. Considering the modelling of business processes and the capture and distribution of knowledge, BPMS are not only important for the engineering of processes but also because it allows the transformation of informal knowledge into formal knowledge and that facilitates externalisation (conversion of tacit knowledge into explicit knowledge), distribution and subsequent internalisation. In this way, BPM has the potential to improve the availability and quality of the knowledge captured, due to its formal nature, increases reuse and consequently, reduces the cost of knowledge transfer (Kalpic & Bernus, 2006; Bitkowska, 2018).

Wu, Kao, & Shih (2010) were also concerned about the transfer of knowledge. According to these authors, if the information system is used to support interaction and collaboration, then, it is capable of achieving the purpose of transferring knowledge through the interaction between the knowledge provider and the receiver, and among those tools included in workflow systems. As explained above, workflow and BPMS systems have many characteristics in common. Therefore, even with greater flexibility and speed than a workflow, BPMS represents a type of technology capable of transferring knowledge throughout the organisation. In addition, according to Bider & Jalali (2016), it is necessary to consider the knowledge built within the information systems that support and control the processes. That knowledge cannot be recorded, nor is it explicit knowledge. People who use the system do not know how it works internally, so it is not tacit knowledge, because it belongs to the system and does not reside in the minds of people. Consequently, these authors refer to this kind of knowledge built within a system as “embedded knowledge”.

In short, organisations are incorporating information systems that support processes, as it is the case with BPMS, which could become useful components for knowledge management. BPMS is an important tool that allows the transformation of knowledge informal or tacit to formal or explicit or,

more specifically, the development of embedded knowledge. They also facilitate their outsourcing and can be shared. BPMS have the potential to establish uniform comprehension criteria and improve the availability and quality of knowledge captured due to their formal nature (Bitkowska, 2018), increase the reuse of knowledge and reduce the costs of their transfer. Summarily, these tools allow knowledge to be encapsulated in business processes (Kalpic & Bernus, 2006).

Definitely, KM allows generating, amplifying and accelerating the creation of value in business processes, which indicates that KM can improve the performance of BPM. Without knowledge or KM the processes could not be optimized, or even created. In short, all knowledge needs to advance through processes, and in the same way all processes that do not apply the improvements allowed by knowledge will be out of context and will not make sense (Paschek et al., 2018). In this way, the integration of KM with business processes makes it necessary to consider the characteristics of both solutions. Systems, capable of propagating knowledge through the tasks of a business process, must focus on the end users of the System and their information needs. In this way, in a study carried out among twelve commercial companies, the perceived usefulness and the satisfaction of the user were determining factors when using a BPMS for KM (Martín-Navarro et al., 2018). From all of the above, we can deduce the importance of combining KM and BPMS

DISCUSSION AND RECOMMENDATIONS

The arguments discussed in this chapter show the importance of KM and how BPMS can play a fundamental role in this management. In this section, recommendations are offered for those managers that decide to successfully implement BPMS for the KM. From the management point of view, studying the BPMS seems to be a consolidated practice. But within this field, it is interesting to note that researchers are quite attracted to the deep-reaching success of the systems (Alam et al., 2015; Antonucci & Goeke, 2011; Bai & Sarkis, 2013; Bălănescu et al., 2014; Filipowska et al., 2009; Gabryelczyk, 2016; Janssen et al., 2015). Since the most studied research topic consists in the evaluation of the tool. Therefore, it seems that determining the success of this type of software is a matter that arouses a lot of attention among the researchers of this discipline. But how is the success of BPMS measured? It seems a delicate issue since, as indicated by Poelmans et al. (2013), in an ideal scenario, the success of the systems could be measured through cost savings or individual performance basis. In practice, however, it is not usual to measure the benefits from this perspective, because this type of data is not usually accessible and the benefits are intangible. However, many authors have learnt that the use of the system, as well as the satisfaction of the end users of a certain technology, serve as measures of success (Asmah, Ofoeda & Gyapong, 2016; Chang, Chang, Wu, & Huang, 2015; DeLone & McLean, 1992; Jiang & Wu, 2016; Poelmans et al., 2013; Sultono, Seminar & Erizal, 2015; Urbach, Smolnik & Riempp, 2011; Wu & Wang, 2006; Yusof & Yusuff, 2013). In this way, studying the end users is considered a good indicator for measuring the success of information systems. Therefore, when evaluating the success of a BPM system, the opinion of an end user is considered an accepted measure.

One of the most used models in the academic literature for measuring the success of the information system is the ISSM (Information System Success Model). This model was proposed by William H. DeLone and Ephraim R. McLean, through their work published in 1992, in the journal, *Information Systems Research*. The objective they pursued with their research was to present an integrated view of the concept of success of information systems (DeLone & McLean, 1992). This model allows measuring the individual and organisational impact of a system based on variables such as satisfaction and use of the

system. At the same time, the quality of the system and the quality of the information are variables that are related to satisfaction and use. Over the next decade, almost 300 articles in specialised journals will refer to the previous success model, which has enjoyed great popularity among researchers, although it has also had its detractors. In this way, the previous authors are aware that numerous studies have tested and validated the success model of the information systems they developed, but they also know that there are authors who have challenged it by criticising it, which has contributed to a better understanding of its success and dimensions. From this learning, it follows that it seems appropriate to add a third dimension called quality of service and continue to maintain the characteristics of the original system in the quality variable of the system, as well as the output in quality of the information. In addition, it seems more appropriate to combine individual impact and organisational impact into a single variable; the net benefits. Also, it is preferable to call it that, rather than impacts, because these can be positive or negative, which leads to possible confusion as to whether the results are good or bad. Therefore, net benefit is probably the most appropriate term that indicates the final success of the variable. From these conclusions, a re-specification of the ISSM was developed (Delone & McLean, 2003).

In order to measure the success of the BPMS, factors that influence the end users must be clearly shown. In this way, it is necessary to analyse factors that determine the use of the BPM tool for knowledge management. Thus, starting from the original model of DeLone & McLean (1992), Wu & Wang (2006) developed a model of success for the KMs. Using this model as a theoretical framework, they introduced the quality of information and knowledge as a measure of success. This work is an interesting framework to determine if BPMS can function as a system for knowledge management. And on the other hand, in 2013, the researchers Poelmans, Reijers and Recker published a study on the operational success of BPMS. The research model was inspired by the updated ISSM, although it was not a replica. In this way, before the quality of the system, they determined a new variable that is the quality of the input, and also divided the attributes of a system between general and specific. The generals are those of any system and consist of reliability, responsiveness and integration. And the specific ones are those typical of the BPMS and assignment of tasks and routing. They also determined that the quality service, which is measured by the training and support received by the user, had an impact on the quality of the system. Another novel aspect is the introduction of a variable that they called dependence on the system, which measures the time the user spends working with the software.

FUTURE RESEARCH DIRECTIONS

The literature review carried out in this paper indicates how it would be possible to manage the knowledge of organisations through a BPMS. However, there are not many works that simultaneously relate to both topics, which opens an interesting way to investigate them together. Especially, future research should be focused on determining the different factors that may impact the utility perceived by users when a BPMS is used for knowledge management, as well as the determinants that make the user feel satisfied with the system.

It is also interesting to test hypotheses through theoretical models that can measure the success of BPMS for KM. As already mentioned, measuring the success of an information system is a complicated issue, but among researchers, it is accepted that it is measured through the use and satisfaction of the users of the tool. For this reason, it is necessary to carry out empirical studies that can provide answers to these questions, using samples obtained from both public and private organisations.

CONCLUSION

Nowadays, knowledge management is a paradigm widely accepted and valued by organisations. Companies need the knowledge that workers have on a personal level to be transferred to the rest of their colleagues. Through this means, they get the best practices in business processes known to all employees, improving the way in which these processes are carried out. That is why managing this knowledge and achieving improvements in processes have become important organisational objectives. BPM was born as a style of business management whose purpose is to constantly improve processes from the beginning to the end with the singular aim of improving customer satisfaction (both internal and external). BPM aims to improve the efficiency and effectiveness of business processes through continuous improvement. In order to carry out good management of the business processes, BPM strives to make the business strategy operational. Although BPM can be carried out in an organisation without making use of technologies, most academics in their discussion of this paradigm, include systems that support the management of business processes. Within these systems, BPMS represent a type of technology capable of automating business processes in a flexible way, coordinating with other existing applications in the company. This flexibility is possible, thanks to the modelling capacity of these systems which are capable of improving a process without the need to reprogram the tool.

The BPMS connect and coordinate the daily tasks performed by the employees of an organisation. In this way, users of the system can use the tool in their daily work, receiving clear specifications of the tasks to be carried out at all times. The design of the business processes carried out through graphic modelling with BPMS allows for the incorporation of the information and knowledge provided by workers who execute the processes. At the same time, the specifications included in the BPMS, when describing how to perform a certain specific task, also allows it to be codified or to explain the expert knowledge of workers participating in the process. This ensures that this knowledge is shared and reflects the capacity of the BPMS for KM.

KEY TERMS AND DEFINITIONS

BPM: Management methodology whose objective is to improve productivity by optimising the business processes of an organisation. It intends to carry out an integral management of the processes, the information, people, and applications that support them.

BPMS: Software that facilitates the management and coordination of tasks within a business process. It uses process modelling rather than programming which makes it a very flexible tool.

Business Process: Set of related activities that follow a logical and specific sequence, with the aim of creating value in an output intended for the organisation, investors or customers.

Information System: Interrelated technological and non-technological elements (hardware, software, communication networks, data, human resources and procedures) according to a certain structure with the objective to capture, debug, store, retrieve, update and process data for the place and time required by the user.

Knowledge: Within an organisation, knowledge is the result of human action on the data and information that the organisation possesses. It is an organisational resource that enables the conversion of information in decisions and actions. It is located in processes, technology and people.

Knowledge Management: Processes and systems aimed at increasing the intellectual capital of the company. It seeks to make tacit knowledge public, actionable, useful, and explicit.

Workflow: Software that automates intelligent movements of information. They allow the coordination, control, and automated communication of the work to be done, both by people and computers in the processes which unlike BPMS needs programming.

INTRODUCTION

Over the past twenty years, technologies using microelectronics for collection, storage, processing, retrieval, transmission, and presentation of data, texts, images, and sound, collectively known as ICT have completely changed all people's activities. The pattern of ICT development and its impact on economic growth and welfare has been reflected in a sequence of theoretical concepts based on a certain degree of understanding of allied transformations (Figure 1). Influence of ICT led at to emergence of a new socioeconomic configuration commonly referred to as the Information Society on the edge of 1990-2000s.

The Information Society is based on extensive use of information and its proliferation into economic and social processes, and engagement of all economic agents – business, governments, and citizens – into the system of communications. Due to inclusion of all these agents in the digital space, big data generated in the digital form has become a factor of economic productivity (Figure 1).

The rapid proliferation of ICT and their impact on all spheres of modern life (see [Ahmad *et al.*, 2004]) – production processes, the interaction of individuals and organisations between themselves and with public authorities, the development of social infrastructure, and privacy issues – has stimulated the interest to statistical analysis of the ICT trends at the global, national and regional levels. Demand for statistical data has been changing along with the transformation of the very nature of various aspects of the economy and everyday life due to its digitalisation, while new measurement opportunities appear out of the progress of digital communications and the availability of large data arrays suitable for statistical processing and analysis. Overall, there is a need for the measuring of the digital technology and digital economy as a whole, while relevant international statistical standards have not yet been developed.

BACKGROUND

The Information Society is usually understood as a society that makes extensive use of information networks and technologies, produces large quantities of ICT goods and services, and has a diversified content industry. Both theoretical and practical issues related to measuring different aspect of information society have been increasingly addressed by many authors during the last two decades (see for example [Gokhberg, Boegh-Nielsen, 2007; Blank, Groselj, 2014; Dolničar *et al.*, 2014; Billon *et al.*, 2016]). As

Figure 1. Evolution of definitions of economic formations and processes related to ICT

Source: compiled by the authors.

we can conclude from existing international statistical practices in this sphere, the key three thematic “pillars” related to the measurement of ICT are as follows (Figure 2):

- The ICT sector and supply of ICT: which industries it includes, how important are they for the national economy, how many enterprises are involved and how many persons are employed, which types of products and services are produced, and what is the total turnover?
- Technical infrastructure, including the penetration rates of landline and mobile telephone networks, the number of computers per inhabitant and the intensity of Internet connections (whether or not a country is ready to become an information-based society).
- ICT demand: which enterprises and individuals are using ICT products and services? Which technologies are being used, and why? What barriers hamper a country’s integration into the global Information Society?

Best practice national and international experiences in the field of Information Society statistics have been accumulated in a set of indicators and methodological guidelines. The Organisation for Economic Co-operation and Development (OECD), Statistical Office of the European Union (Eurostat), International Telecommunication Union (ITU), and United Nations Educational, Scientific and Cultural Organization (UNESCO) Institute of Statistics play the leading roles in these efforts (Table 1).

Statistical standards are produced by the dedicated working groups at the international organisations in close collaboration with national statistical services, in particular: the OECD Working Party on Measurement and Analysis of the Digital Economy, Eurostat Working Group on Information Society Statistics (WG ISS), ITU Expert Group on Telecom/ICT Indicators, ITU Expert Group on ICT Household Indicators. Implementation of the international statistical standards at the national level is usually voluntary; however, in order to ensure full-scale participation in international data exchanges, and to be able to assess the country’s positions vis-a-vis the global trends, most nations follow the international recommendations on measuring ICT. The most recent agenda of those working groups is focused on methodological approaches and standards for measuring the new phenomena related to the digital technologies and digital economy.

INTERNATIONAL STANDARDS FOR THE INFORMATION SOCIETY STATISTICS

Information Society statistics is one of the newest branches of socioeconomic statistics aimed at measuring all aspects of activities related to production of ICT goods and services, proliferation and usage of ICT in the economy, social and public sectors, and private life [HSE, 2014].

Information Society statistics is aimed at the following objectives:

- regularly collecting and processing relevant data to provide a basis for studying ICT development trends and assessing policies aimed at promoting the Information Society;
- conducting international comparisons, calculating international rankings;
- communicating reliable and comprehensive data to users.

Table 1. Existing international standards for ICT statistics

Areas covered by international statistical standards	References

Core list of indicators on ICT access and use by households and individuals	Partnership, 2016

Source: compiled by the authors.

The main international agency which has initiated and pursued development of relevant methodologies, since the very beginning, has been the OECD. Several issues of the OECD Guide to Measuring the Information Society were published, summarising the experience accumulated over the years (2005, 2009, the latest edition – 2011). The 2011 Guide presented basic concepts, definitions, and classifications, and included practical recommendations on collecting internationally compatible statistical data in the following areas [OECD, 2011]:

- **the Information Society:** the conceptual model in statistical terms;
- **ICT products** (definitions and classifications relating to ICT goods and services, measurement of international trade in ICT goods, prices and quality of ICT products);
- **ICT infrastructure** (access, quality, investments, tariffs);
- **ICT Supply** (the ICT sector and its impact, other suppliers of ICT, ICT patenting activity);
- **ICT demand by businesses** (the OECD model survey of ICT usage by businesses including statistical standards for e-business and e-commerce, business ICT investment and expenditure, economic impacts of ICT investment and use);
- **ICT demand by households and individuals** (the OECD model survey of access to and usage of ICT by households and individuals; includes a discussion of e-commerce and social and economic impacts of ICT use by households and individuals);
- **Content and Media sector** (statistical issues related to the information and electronic content, and more recent work on defining the content and media sector and its products);
- **The international scene and the road ahead** (overview of the international activities on measuring ICT as well as arising future challenges).

Currently most of the countries and many international organisations apply, to a different extent, the OECD-proposed methodological approaches to statistical surveys and analysis of the ICT sphere.

Basic OECD statistical standards for measuring ICT usage by businesses, e-commerce, and households' and individuals' access to and usage of ICT were harmonised with statistical methodology and data collection practices adopted by the EU countries. In its turn, the European experience prompted further development of the OECD and other international organisations' activities in this area. Methodological issues are dealt with by the Eurostat, jointly with national statistical services (the WG ISS is responsible for this work). The Eurostat mostly concentrates on coordinating two major surveys: ICT usage in organisations (the Eurostat Model for a Survey on ICT Usage and e-Commerce in Enterprises) and in households (the Eurostat Model for a Survey on ICT Usage in Households and by Individuals). These surveys are based on Model Questionnaires and the accompanying methodological guidelines for their implementation. The surveys are developed in close collaboration with the EU Member States and the OECD and are adapted to the changing needs of users and policy makers [Eurostat, 2016a].

The ITU provides definitions, which serve a basis for producing ICT infrastructure indicators. Its Handbook [ITU, 2011] is a key reference document for the collection of internationally compatible indicators on telecommunications/ICT based on administrative sources (i.e. supply-side data mainly provided by telecom operators). Due to the rapid development of the telecommunications sector, indicators have to be regularly adjusted. The impressive growth and transformation of the mobile communications and the Internet sector made it necessary to review the existing definitions. The current version of the Handbook contains definitions and methodological clarifications for 81 internationally accepted indicators and corresponding sub-indicators proposed by the ITU. It fully reflects the main aspects of monitoring the telecom infrastructures: landline and mobile telephone communications, Internet, tariffs for communication services, investments in telecommunications, and other relevant indicators.

Activities of UNCTAD refer to collecting and analysing national statistics, as well as providing consulting and training services to countries willing to produce internationally compatible ICT indicators. "Manual for the Production of Statistics on the Information Economy" [UNCTAD, 2009] contains recommendations for national statistical offices on methodological and practical aspects of statistical surveys of ICT development and application in the economy. It includes definitions, data sources, and methodologies for calculating important indicators, questionnaires and methodological issues commonly arising in the course of relevant statistical surveys, together with suggestions on dissemination of statistical information.

Following the 2003 World Summit on the Information Society in Geneva, the Partnership on Measuring ICT for Development (Partnership) was established, and started its official operations in 2004. The Partnership is an association of international and regional organisations involved in studying ICT development trends. Its current members are Eurostat, ITU, OECD, UNCTAD, the United Nations Department of Economic and Social Affairs, UNESCO Institute for Statistics, World Bank, and four UN regional commissions [Partnership, 2010].

The Partnership strives to produce internationally comparable and reliable ICT statistics. To achieve this, its members participate in developing and maintaining a Core List of ICT indicators. Other activities include compilation and dissemination of ICT data, and provision of technical assistance to help statistical agencies collect data for the Core List of ICT indicators. Its first edition was approved by the UN Statistical Commission in March 2007. There were 41 indicators on ICT infrastructure and access, ICT usage by households, individuals, businesses, and in the ICT sector, and on trade in ICT goods.

In 2008, taking into account new methodological guidance by the ITU and UNCTAD and the UNESCO proposals¹, the Partnership's List was reviewed, with Core Indicators on ICT in Education

added. Other changes to the List were updated indicators, elimination of differences between basic and core indicators, and more precise definitions of the terms used in the indicators, to reflect the revised international statistical standards. In 2012, a set of core indicators on e-government was added to the List [UN, 2012]. The latest revision of the Core List was based on a supply/demand conceptual model of the Information Society and covered such areas as the ICT infrastructure and access, access to and use of ICT by households and individuals, the use of ICT by businesses, the ICT sector, trade in ICT goods, ICT in education, e-government, and electronic waste [UN, 2014].

The last two decades have demonstrated an explosive growth of online economic activities including the Internet access provision and Internet-based services. Therefore, a new direction of statistical analysis has been developed – the assessment of the contribution of the Internet economy to GDP. A variety of studies covered the direct impact of the Internet on the economy [BCG, 2014; McKinsey, 2011; Bakshi, 2016], indirect economic impact of the Internet [Stiglitz, Sen, Fitoussi, 2009; BCG, 2010] as well as its social impact [OECD, 2013; Shah, Kwak, Holbert, 2011; Morton, 2006; Greenstein, McDevitt, 2011].

INDICATORS OF ICT AND CONTENT-RELATED ACTIVITIES

All ICT and content-related activities (the so called Information Economy) are divided into two sectors: the ICT sector and the Content and Media sector.

Figure 3. OECD Information Economy sectoral and product definitions

Year	Sectoral definitions		Product definitions		
1998	First ICT sector definition (based on ISIC Rev. 3)				
2002	Revised ICT sector definition (based on ISIC Rev. 3.1)		First ICT goods classification (based on HS 1996/2002)		
2003					
2007	Second ICT sector definition (based on a late draft of ISIC Rev. 4)	First content and media sector def. (based on a late draft of ISIC Rev. 4)	First ICT services classification (based on an early draft of CPC Ver. 2)		
2008			First content and media product class. (based on a late draft of CPC Ver. 2)	Revisions to 2007 ICT services (based on a late draft of CPC Ver. 2)	Second ICT good classification (based on a late draft of CPC Ver. 2)
			ICT product classification		
			Information economy product classifications		
2010			Information economy product classifications (Correspondence: CPC Ver.2 HS 2007 – HS 2002)		

Statistical measurement of the ICT sector is centred around identification of the ICT-related activities (industries) and goods and services produced in this area.

Yet in 1998, the OECD adopted a definition of the ICT sector based on identifying and selecting ICT activities: in manufacturing, the products of an activity must be intended to process and communicate information, or to transmit and display information. They may also use electronic processes to detect, measure and/or record physical phenomena, or to control a physical process. In service activities, the products must be intended to enable the processing and communication of information through the use of electronic means [OECD, 2011]. The selection was based on the UN International Standard Industrial Classification (ISIC Rev. 3) and included only whole activities, not parts (*Figure 3*).

The latest changes were made in 2008, in line with the adoption of the modified ISIC Rev. 4. These were particularly relevant to the services sector. In the end, the scope of the ICT sector definition was reduced: the relevant industries' products and services must be intended mainly for data processing using electronic communication means, including data transfer and provision, or for supporting such activities.

Although in the new definition "electronic processes to detect, measure and/or record physical phenomena, or to control a physical process" were excluded, the list of functions belonging to the ICT sector was extended due to the coverage of a broader range of newly emerged service activities. The ICT sector definition was introduced as an official alternative analytical aggregation in the ISIC Rev. 4. The activities (industries) in the ICT sector can be grouped into ICT manufacturing industries, ICT trade industries and ICT services industries.

The ISIC Rev. 4 industries that comply with the above definition are as follows:

ICT Manufacturing industries

- Manufacture of electronic components and boards;
- Manufacture of computers and peripheral equipment;
- Manufacture of communication equipment;
- Manufacture of consumer electronics;
- Manufacture of magnetic and optical media.

ICT trade industries

- Wholesale of computers, computer peripheral equipment and software;
- Wholesale of electronic and telecommunications equipment and parts.

ICT service industries

- Software publishing;
- Telecommunications, included Wired telecommunications activities, Wireless telecommunications activities, Satellite telecommunications activities, and Other telecommunications activities;
- Computer programming, consultancy and related activities, included Computer programming activities, Computer consultancy and computer facilities management activities, and Other information technology and computer service activities;
- Data processing, hosting and related activities; web portals, included Data processing, hosting and related activities, and Web portals;
- Repair of computers and communication equipment, included Repair of computers and peripheral equipment, and Repair of communication equipment [UN, 2008].

The Classification of ICT Products is based on the same principles. It enables statistical agencies to produce two types of data: about production, based on the Central Product Classification (CPC) Ver. 2, and about imports (exports) of relevant products, based on the Harmonised System (HS) (*Figure 3*).

In addition to the ICT product classification, there is an obvious need for a harmonised classification of ICT services. However, due to a very rudimentary state of the earlier services classification, structuring new, rapidly developing service activities (such as web hosting or software initialisation, etc.) only became possible at the end of 2006, based on the new CPC Ver. 2 [OECD, 2011], which provided a detailed structure of the CPC Ver. 2 subclasses linking them with the ISIC Rev. 4 and HS 2007.

An internationally agreed definition of the Content and Media sector (comprising organisations whose economic activities involve production, publication, and/or dissemination of content) was developed in 2007–2008 on the initiative of the OECD, based on the ISIC Rev. 4. The sector covers the following industries:

- Publishing of books, periodicals and other publishing activities, included Book publishing, Publishing of directories and mailing lists, Publishing of newspapers, journals and periodicals, and Other publishing activities;
- Motion picture, video and television programme activities, included Motion picture, video and television programme production activities; Motion picture, video and television programme post-production activities, Motion picture, video and television programme distribution activities, and Motion picture projection activities;
- Sound recording and music publishing activities;
- Programming and broadcasting activities, included Radio broadcasting, and Television programming and broadcasting activities;
- Other information service activities, included News agency activities, and Other information service activities n.e.c. [UN, 2008].

The core indicators of the ICT sector and Content and Media sector are value added and employment as well as their percentages in the respective national totals.

INDICATORS ON ICT INFRASTRUCTURE

Statistical surveys of ICT infrastructure describe activities of telecommunications (as a segment of the ICT sector) and of broadcasting organisations as a segment of the Content and Media sector. The surveys include communication services output, revenues, and personnel.

ICT infrastructure indicators cover access to the Internet, telephone, telegraph, satellite communications; radio communications; the Internet and mobile traffic, including numbers of internet users with mobile, fixed, and broadband access, mobile subscribers, etc.

Indicators measuring accessibility of communication services, such as tariffs for local landline telephone calls, mobile communications, and landline broadband Internet access, are also given necessary attention.

Due to convergence of networks, services, and devices, indicators on ICT infrastructure now include television indicators. Development of the television segment is measured by availability of mandatory TV channels and the population's coverage by digital on-air and cable TV broadcasting.

These indicators are important not only to measure the level of ICT availability, but also for the estimation of the ICT productivity [Byrne, Fernald, Reinsdorf, 2016].

INDICATORS ON ICT USAGE BY BUSINESSES, HOUSEHOLDS (INDIVIDUALS), AND THE SOCIAL SPHERE (HEALTH AND EDUCATION)

The Eurostat collects data on the Information Society in the EU, focusing on the availability of ICT usage by individuals and within households [Eurostat, 2016b] and by enterprises [Eurostat, 2016c].

The main areas of statistical surveying of ICT usage in the business sector are availability of ICT, objectives and results of the Internet usage.

Statistical surveys of ICT usage by households and individuals allow to measure availability of and access to ICT; use of mobile phones, computers, and the Internet (places of access, purposes and frequency of usage); ICT-related skills, etc.

Internationally harmonised indicators of ICT usage by individuals are intended to reflect variations across countries and specific population groups in the same country, by the following parameters:

- application of cutting-edge technologies to provide higher-quality broadband Internet access;
- use of the opportunities provided by the Internet;
- replacement of conventional forms of socialisation, work, leisure, information search, shopping, etc., with new Internet-based formats;
- factors promoting or hindering ICT proliferation among the population.

Particular attention is devoted to e-commerce and e-government indicators, both with respect to enterprises and individuals.

E-commerce is defined as the sale or purchase of goods or services conducted over computer networks by methods specifically designed for the purpose of receiving or placing orders. The payment and the delivery of the goods or services do not have to be conducted online. E-commerce transactions exclude orders made by manually typed e-mail messages [Eurostat, 2015].

E-government is referred to as electronic contacts via the Internet with public authorities and allied public services. Contacts through manually typed e-mails should be excluded. Contacts and interactions with public authorities and public services include websites concerning citizen obligations (e.g. tax declarations, notifications of moving), rights (e.g. social benefits), official documents (e.g. ID cards, birth certificates), public educational services (e.g. public libraries, information on the enrolment in schools or universities), public health services (e.g. services of public hospitals) [Eurostat, 2015].

Surveys on the ICT usage in the social sphere, health, and education sectors have a structure similar to those on the ICT usage in the business sector. They also cover certain specific issues, such as, for the health sector – development of telemedicine, application of ICT to create and maintain medical registries and databases, provide electronic services to patients, etc.; for education – availability of various kinds of ICT in all types of educational institutions, along with conditions for the efficient application of ICT in teaching, ICT usage by teachers and students, introduction of new ICT-based teaching formats and techniques, etc.

NEW FOCUS OF STATISTICS – MEASURING DIGITAL ECONOMY

Digitalization of businesses, households, and the government leads to radical changes in the scope and scale of the demand for official statistics [Gokhberg *et al.*, 2018]. This also refers to the measurement of the new socioeconomic phenomena (such as, for example, the substitution of conventional (i.e. analogue) processes with digital ones²) related to the digital economy [Gokhberg, 2019].

Official statistics has to respond to the new challenges and provide evidence-based answers on the issues like:

- application of and demand for digital technologies;
- availability of and demand for digital technology-related products and services;
- the rate of the digital economy development and its contribution to economic growth and societal wellbeing;
- digital technologies' impact on business performance, labour productivity, and other socio-economic parameters;
- government efficiency in the digital economy, including the effects of digital technologies on the quality of government services and relations between the state, the public, and businesses;
- the effectiveness of public expenditures on implementing government digital economy policy and its impact;
- assessment of national advantages and barriers hindering competitiveness in the global digital economy, etc.

OECD designed an inventory of existing indicators drawn from a wide range of areas statistics, including those on education, innovation, entrepreneurship and economic growth, against current digital economy policy issues, as reflected in the OECD Internet Policy Principles [OECD, 2011b]. By doing so, it identified gaps in the current measurement framework and assessed progress achieved to cover them. In this respect, advancement of the measurement agenda is the overarching objective of measuring the Digital Economy [OECD, 2014, 2019].

The first attempts to measure new areas related to digital technologies have been already made. An example is statistical surveys of organisations using cloud services, robotics, and 3-D printing [Eurostat, 2018]. Another case is introduction of indicators of demand for cloud services into the existing surveys of ICT use by households [Eurostat, 2018].

SOLUTIONS AND RECOMMENDATIONS

Despite the above mentioned extensive methodological groundwork, measurement of ICT and the digital economy remains a substantial challenge to the official statistics. Many traditional approaches have become obsolete against the background of the rapid changes in this area, while some new issues are still outside the existing measurement frameworks.

For example, the broadband Internet definitions require revisiting. Broadband is defined as a service providing download speeds of at least 256 Kbit/s [ITU, 2011]. In order to adequately reflect the development of the high-speed Internet for broadband access the lower boundary should be set at a speed of at least 2 Mbit/s.

The next point refers to the surveys of ICT usage by households and individuals. For this purpose, international organisations typically consider all people living on the same premises, both related and unrelated to each other, as a household, if at least one of them belongs to the target population group. The recommended age range for the surveyed population is 16–74 years. National statistical offices may collect data about individuals outside this age group (they might be particularly interested in the ICT usage patterns by people aged above 75 years). Many OECD member countries have actually extended the age coverage and also survey individuals under 15. In about a half of the OECD member states, the target group's age range was extended to 10–72. Some countries, such as Korea, Mexico, and the USA, even survey children aged 3–6. Many countries have also eliminated the upper age limit of the target group. Inclusion, worldwide, of increasingly large population groups into the survey samples is explained by the wide penetration of information technologies into the people's everyday life at any age.

It is recommended to introduce international standards in statistical methodologies in order to avoid an existing significant data distortion (currently – up to 20–30%), which complicates cross-country comparisons on an equivalent basis and production of reliable international statistics. It is also recommended to introduce standardised approaches for data collection on ICT infrastructure indicators, such as the revenues from all telecommunication services; from mobile communications; and investments in telecommunications, in particular in developing countries.

FUTURE RESEARCH DIRECTIONS

Methodological approaches and statistical indicators described above should be seen as the basic ones. They are quite suitable for application in practically all countries. At the same time, ICT-related processes are inherently so dynamic, and the changes are so rapid that statistical measuring techniques need to be regularly updated and improved. Conventional statistical monitoring of ICT should be complemented with experimental indicators reflecting the digital economy processes, including its impact on economic growth (e.g. quantitative assessment of the Internet-induced openness's consequences in innovation, entrepreneurship, labour productivity, etc.), societal wellbeing, and environment; trust, personal data protection, privacy risks, and cybersecurity [OECD, 2016].

Among the perspective future research directions there are statistical methodologies for the following issues [Gokhberg, 2019]:

- Expenditures on digital economy;
- Creation and dissemination of digital technologies (including R&D, protection of intellectual property rights, technology transfer, innovation, digital engineering);
- Human resources and labour market; digital skills; employment, including the remote and platform-based ones;
- Use of digital technologies in sectors of economy and social sphere (e.g. in education, health, and social services);
- Production of digital content (digital products and services: images, video, audio, texts, games, etc.);
- E-commerce;
- Foreign trade in digital technologies and relevant goods and services;
- Digital trust (cybersecurity, protection of personal data);
- Digital equality and inclusion of the socially vulnerable groups of population (disabled, retired, inhabitants of remote areas, etc.).

Another important area for statistical activities is related to the rapid increase in new (e.g. big) data sources, in particular those generated by digital equipment in industry and households. International organizations and national statistical offices are looking forward into innovative ways to utilize big data as a source, which may complement to or substitute for traditional statistics allowing to overcome substantial data gaps [UN, 2016; Gokhberg et al., 2018].

CONCLUSION

Digital technologies permeate countless aspects of the world's economy, impacting sectors as varied as banking, retail, energy, transportation, education, media or health. ICT is transforming the ways social interactions and personal relationships are conducted, with landline, mobile and broadcast networks converging, and devices and objects increasingly connected to form the Internet of Things. Development and diffusion of artificial intelligence, robotics, advanced manufacturing technologies, virtual and augmented reality, wireless communications are also the areas which are more and more frequently mentioned for the measurement purposes.

This leads to an increasing demand of businesses, society and the government for respective statistical data. To meet this demand, a new generation of internationally harmonised statistical standards is required to provide national statistical offices and policy makers with more advanced methodologies of statistical measurement of the digital economy, envisaging relevant definitions and classifications, efficient data collection and processing procedures, and modern channels and formats of data visualisation and dissemination between various categories of users.

KEY TERMS AND DEFINITIONS

ICT Sphere: Supply, demand, and usage of ICT.

ICT Usage Statistics: A sub-area of information society statistics studying all aspects of activities involving application of ICT in the business sector, social sphere, public administration, households, and by individuals.

Information and Communication Technologies (ICT): Technologies using microelectronics for collection, storage, processing, retrieval, transmission, and presentation of data, texts, images, and sound (HSE, 2014).

Information Industry Statistics: A sub-area of information society statistics studying all aspects of the ICT and content-related activities.

Information Society Statistics: The newest branch of social and economic statistics aimed at studying all aspects of activities related to the production of ICT goods and services, distribution and usage of ICT in the economy, social and public sectors, and private life (HSE, 2014).

International Statistical Standards for Measuring ICT: A set of internationally accepted recommendations on statistical surveying of information society, specifying requirements to statistical data and describing methodology for building basic indicators, based on harmonisation of national statistical standards.

International Statistics: Harmonised statistical methodologies and data collected and published by international organisations based on standardised programmes, to conduct regional and international comparisons.

ENDNOTES

¹ UNESCO develops harmonised methodological approaches to measuring ICT usage in education, including development of relevant definitions and concepts and sets of internationally compatible indicators. These include applications of radio, TV, and the Internet in education processes, training of ICT professionals, etc. The main principles for building such a system of indicators are described in UNESCO (2009).

² For example, digital transactions such as online purchases and deliveries should be counted separately from the “conventional” trade.

Organizational Knowledge of Digital Economy in Transformation, in Big Data, and in Internet of Things

INTRODUCTION

As it is well known, the management issues, related to planning, searching, production, distribution and delivery of products or services (from a place from their production to a place of their consumption) are expressed by the term ‘Supply Chain Management’ (SCM). Currently, this term is a promised standard that is officially accepted. Modern SCM consists of popular business processes which implement newest technologies and innovative solutions. The main goal SCM is to be highly efficient supply management, when the product is available where and when its consumer needs it.

SCM is implemented as a technology that includes various tools, including artificial intelligence, performing machine learning with cognitive computing, which makes it possible to support constant analytics and transformation between the cyber-physical real environment and the digital space. In fact, SCM provides the transformation of traditional linear supply chains into intelligent, scalable, customizable, and fast delivery networks. Additionally, for ordering the technology to work, two more components are needed: the correct economic business models (under the conditions of the digital economy, it can be named as a joint economy) and mechanisms for providing trusted relations in business (that are grouped around the system of blockage or Internet values). In the chapter, avatar-based supply chains are considered also as an expert knowledge source for smart solutions to develop sustainable urban systems. The avatar-based supply chains as expert knowledge is a new concept that includes planning, searching, production, distribution and delivery of Mkrttchian’s digital avatars from the place of origin to consumption (Mkrttchian & Aleshina, 2017). This kind of supply chains are very different from the traditional one, because they relate to a specific product-expert knowledge, which is formed from electronic data, distributed in the Internet. The data belong to business partners and value-added service providers, operating in a general digital economy paradigm using blockchain technologies (Blockchain..., 2016).

The chapter focuses on analysis of business relations and their integration into sustainable urban systems. The supply chains of the 21st century are more complex and dynamic than ever before. Companies, that form the real value of business and, in general, of competitive global economy, need to improve their management in such aspects as inventory, costs, assets and introduction of new products. The improvement cannot be essential without use of the digital supply chains, which, working together with the technology of blocks, will transform the world of modern logistics. Even largest organizations

DOI: 10.4018/978-1-7998-3473-1.ch035

lack the capacity, resources and knowledge to deploy end-to-end information integration in their supply networks. The networks consist of many components, or “supply chain nodes”, that are connected through flow paths. Inventory and products: the use of these flow paths has the ultimate goal of ensuring that customers’ needs are realized in a most beneficial way. Governments and companies have now the urgent need of cooperation to accelerate such integration within the framework of the Digital Supply Chain (DSC) concept, using the principles of joint economy and blockbuster technology. Collaboration in the DSC creates a multi-stakeholder environment for different needs and objectives, in which large companies are integrating with their main suppliers. Even competing companies are forced to cooperate for integrating the entire supply chain.

Value-added service providers play different roles, but their cooperation, supported by the common interests, should establish a common trusted environment. For the success of this kind of joint activity, DSC should offer the company competitive advantages, but for this a number of prerequisites must be realized: intermediate products should be quickly integrated; logistics partners should make deliveries using the tracking and visibility functions; and information and communication technologies (ICT) should be introduced in all the business processes. Joint activities are possible only on the basis of expert knowledge, which can be supplied, for example, by Mkrttchian’s digital avatars (Mkrttchain, 2013).

Within the framework of the Fourth Industrial Revolution, not only the list of end-to-end technologies is changing, but mental and methodological approaches to the development of jerk scenes are radically transformed. It is especially noticeable in the sphere of urban economy. It is obvious that the actively recovering industry in the coming years will become one of the main drivers of economic growth, which will have an impact on into sustainable urban systems. The main driver of breakthrough development in these conditions will be promising fast-growing industrial companies that have the highest leadership potential global markets. These are domestic private high-tech export-oriented companies, leaders in terms of development rates. Within the rating of Texas, 62 such companies were selected (Mkrttchian, et al, 2019). In 2018 it is planned to select an additional 30 companies. It is these circumstances that determine the relevance of the research in this chapter.

BACKGROUND

The advantages of Mkrttchian’s digital avatars (Mkrttchian et al, 2019) include profitability of services and the creation of value of joint activities that are beneficial to many ecosystem entities (Chenyshenko, Ruzich, 2013), including firms and their suppliers, employees and customers will be discussed below. Development of the avatars, as a special branch of computer science, has been booming in recent years (Arifovic et al., 2010; Dawid & Fagiolo, 2008; LeBaron & Winker, 2008). For the considering problem, the basic model “Triple H Avatars” was proposed in (Mkrttchian, 2013). A parallel trend in the computer science is multi-agent models and methods of computer simulation (Gilbert & Troitzsch, 2005), which are useful for solving such problems as forming an “environment” algorithm, which unites a set of agents or avatars into a system.

The digital avatar supply chain can be defined as a set of avatars of three or more subjects (i.e. organizations or individuals) directly involved in downstream flows of products, services, finance, and / or transfer of information from source to client. This definition emphasizes the role of information flows between firms, especially in business and business areas and process levels. The digital avatar of Mkrttchian refers to the software industry or to the development of programs. As in any production, there are tools in programming that allow you to produce certain parts (blocks), platforms (develop-

ment environments) for assembly, operating conditions, testing and product life cycle. And of course the combination of the virtual, digital and physical worlds that were published in the IGI Global publishing house in 2010-2018.

Since the governments of all countries today absolutely strictly support open source software development, Mkrttchian's digital avatars are written exactly with this code. The main reasons for this are to avoid software silos or create closed systems for interaction, to take advantage of the economic advantages of open source code and to clearly represent security issues. Open Source Software (OSS) is a computer software with its source code available with a license in which the copyright owner grants the rights to study, modify and distribute the software to anyone and for any purpose. Open source software can be developed in conjunction with the public. According to scientists who studied it, open source software is a prime example of open collaboration. Development of open source software or joint development from several independent sources creates an increasingly diverse field of design than any company that can develop and maintain a long-term perspective. And this is also one of the phenomena of a joint digital economy with its own and very significant indicators (Tolstykh, 2018).

Transition process to the digital economy was predicted quite long ago (Tapscott 1996; Brynjolfsson, Kahin, 2003). There are three levels of its development: markets and industries; platforms and technologies; environment (Bershadsky, et al, 2017). Suppliers and consumers interact at the first level. Development of markets and sectors of the economy take place at the second one. The third level is an environment for forming conditions for the development of "cross-cutting" technologies to operate in the global market and to form infrastructure for the digital economy (Mkrttchian, et al, 2016).

New technologies and processes are investigated within the concept of Industry 4.0, which supposes the use of network approach that is based on the ability of creating smart products, such as powerful, flexible and affordable Cyber Physical Systems' applications with various production types. The Internet of Things (IoT), Big Data and blockchain are three main trends that could combine to create an entirely new methods and tools for managing regional innovation system and provide their economic development (Kohler et al., 2009). This development looks at the 'art of the possible' and this new way of thinking could provide powerful ways for a business to run autonomously (Sun, et al., 2018).

Blockchain technology gives an alternative possibility, which allows to a single participant to "out-source" management, communications and scalable infrastructure problems to the peer-to-peer network (Swan, 2015). Instead of using a central server, a distributed public ledger will be maintained to store the transaction records and every node will possess a copy of this immutable public ledger. The "scalability" feature of blockchain can be used in the IoT world (Asharaf and Adarsh, 2017). The blockchain method is gaining popularity for elaboration of "self-developing" information systems of various profiles (Mohan, 2017). The use of intelligent avatars is based on semantic analysis of distributed information, so we need in blockchain-*knowledge* base (Zhang et al., 2017).

The transition to advanced digital, intelligent production technologies, robotic systems, new materials and design methods, the creation of systems for processing large amounts of data, machine learning and artificial intelligence. Big data technique for data storage, searching and analytics is a new achievement in the field of innovation, research and development (Chen and Zhang, 2014; Gandomi and Haider, 2015) Big data and its emerging technologies made essential changes in the business standards, as well as changed traditional data mining and business analytics (Sun, et al., 2018; McAfee and Brynjolfsson, 2012). The intelligent big data analysis becomes the disruptive technology for the age of trinity in terms of healthcare, web services, service computing, cloud computing and social networking computing (Ramzan et al., 2018).

MAIN FOCUS OF THE CHAPTER

Issues, Controversies, Problems

The purpose of this chapter is to achieve a global competitiveness in high-tech markets by dynamic industrial enterprises, increase labor productivity, improve the quality of life of the population, create innovative and active human capital, and increase the number of people employed in non-primary sectors by developing methodological bases and corresponding theoretical and practical tools for developing and implementing scenarios of breakthrough development. As a result of the analysis of Issues, Controversies, Problems, we established that the main focus of our chapter will be directed to the following tasks, which will determine the purpose of our research. The purpose of the research in this chapter is predetermined the need for the formulation and solution of the following tasks:

- To form the original concept of managing fast-growing industrial enterprises for the purpose of breakthrough development and technological breakthrough in the entire Russian industry.
- To develop a methodology and principles for the breakthrough development of fast-growing industrial enterprises in conditions of digital transformation.
- To propose a conceptual model and management system for the breakthrough development of fast-growing industrial enterprises.
- To carry out a synergetic modeling of the breakthrough scientific and technological development of companies - national champions.
- To substantiate the benchmarks, develop and test scenarios for the breakthrough development of fast-growing industrial enterprises.
- To offer a compliance-management system for the problems-calls of industrial enterprises.
- Propose the procedure for the introduction of digital counterparts and on their basis digital shadows in industrial enterprises.
- Develop and test the methodology for assessing the KPI breakthrough development of fast-growing industrial enterprises.
- Develop a program for the digital transformation of industrial enterprises.
- The focuses on the analysis of business relations and this integration into sustainable urban systems. The supply chains of the 21st century are more complex and dynamic than ever before.

The goal of clearly articulating these tasks, according to the authors, is to help readers understand the logic of the decisions made, and if necessary, readers can refer to the list of additional readings.

Open source software has long become a ubiquitous industrial production and business. There is, for example, a tremendous amount and variety of open-source software components and third-party components that arise in every software development environment in the world. With proper use and management, these components are a huge source of energy to accelerate innovation in the digital economy. Otherwise, they are directly related to security vulnerabilities, licensing risks, huge improvements and wastes, as in any production. The digital avatars of Mkrtchian's are work only on the basis of expert knowledge. Components are delivered to organizations through supply chain software that work is with many parallel traditional production supply chains. Therefore, a huge network of component suppliers creates 1000 new projects and provides 10,000 new versions per day. The software industry has already produced as many as tens of millions of products and their number is continuously increasing. Within it, OSS has the largest growth dynamics. The number of employees in the software industry is enormous

and is estimated at tens and hundreds of millions of people. But the laws of reducing costs and improving profitability are also valid in it. We need new innovative technologies and, in structure, they should resemble a system of blockchain.

The scientific novelty of the research is the development of theoretical and practical approaches to the construction of scenarios for the breakthrough development of fast-growing industrial companies, the implementation of which will provide the necessary scientific and technological and socio-economic breakthrough in priority and promising in the context of new markets industries of Russian industry (Karapetyants et al., 2017).

The methodological basis for the study is the integration of the systemic and synergetic approaches, taking into account the most important dialectical regularities. The basis of this approach is the methodology of system analysis, which serves as a methodological framework combining all the necessary methods, research methods, activities and resources to solve the research problem. System analysis organizes our knowledge of the problem in such a way as to help choose the best strategy for its solution or to predict the results of several alternative strategies that seem appropriate to eliminate the contradictions that gave rise to the above-mentioned research problem. In the framework of the system approach, it is proposed to use the method of systemic potential as one of the methods of system dynamics, used to study complex adaptive systems, adapting it to study the development processes in the economic system. Theoretical and methodological basis of the research will be general scientific empirical-theoretical methods of system analysis, abstraction, analysis and synthesis, induction and deduction, analogy, modeling, concretization, historical and logical methods of research. Specific scientific methods will be applied to continuous and selective observation, expert methods, content analysis, cluster analysis, methods of detailing, comparative, factor and correlation-regression analysis, optimal solution method, predictive extrapolation method, mathematical apparatus of genetic algorithms, SimBrain neural simulator, the software product IBM SPSS Statistics Subscription, as well as standard (Evolver and Risk companies Palisade Corp.) and the original add-ins MS Excel.

The study of the processes of interaction of economic agents in the economic system necessitates the use of a neo-institutional approach, which makes it possible to institutionalize the basic incentive to strengthen the interaction of economic agents, namely, the level of transaction costs of economic activity. Reducing the level of transaction costs for economic activities, provided by the digitization of social and economic processes, will increase the efficiency of the functioning of formal institutions, and will enable the unrealized potential of the economic system to be used. Ultimately, the achievement of the optimal level of costs of economic activity will make it possible to launch the process of self-development of socio-economic systems. Thus, the use of the system approach will allow to correctly structure and establish the relationships between the elements and development factors, and also to identify bottlenecks in the development of the economic system. The synergetic approach will make it possible to take into account the dynamic aspect of the development of the innovation system, such categories as the growing complexity, uncertainties, etc., which are inalienable, which are inherent attributes of economic activity, and allows it, on the basis of cooperative interaction of its participants, to generate new criteria, components and structures that facilitate the adaptation of the system to changing conditions.

Within the framework of this methodological approach, dialectical methods of cognition will also be used, providing a comprehensive and objective character of the study of the problem, logical, structural-functional, strategic, evolutionary, factor analysis, modeling, economic-statistical and other methods.

At all stages of the study, the use of the content analysis method with appropriate tools will be appropriate. For the analysis of foreign experience, historical and logical methods of research will be used. The basis of theoretical methods is the methods of organization and functioning of systems with one of the

most powerful methods of adaptation - self-organization. To collect information from economic agents on the level of transaction costs of economic activity, it is proposed to use sociological research methods. The tools for conducting a survey will be a poll program, the design of a representative sample, and the form of the questionnaire. For the assessment of transaction costs, mathematical models of fuzzy logic and metric are supposed to be used. This is necessary to evaluate the various in nature and essence of both quantitative and qualitative factors and parameters under conditions of nonlinearity and uncertainty (under conditions of ambiguous, asymmetric information). Metric methods provide the opportunity to carry out measurements under such conditions.

SOLUTIONS AND RECOMMENDATIONS

The mathematical apparatus of the theory of fuzzy sets provides new tools and possibilities for processing qualitative factors and parameters that have high uncertainty. The analysis of the collected empirical data will be carried out using the IBM SPSS Statistics application package.

Thus, the use of the integration of a number of methodological approaches to the research problem presents in aggregate a constructive tool that allows to solve the problems posed in the study:

- The original author's concept of managing fast-growing industrial enterprises, containing classification characteristics and content characteristics, to ensure global, innovative, inclusive, proactive and sustainable breakthrough development of Russian industry.
- Methodology for managing the breakthrough development of fast-growing industrial enterprises on the basis of laws and development principles, which includes a set of theoretical foundations in terms of hypotheses, applied theories and basic approaches, basic organizational and management mechanisms and basic efficiency assessments.
- Conceptual model and management system for the breakthrough development of fast-growing industrial enterprises at mega-, macro-, meso- and microlevels, which allows preparing all actors of the ecosystem for effective sustainable development in accordance with the goals set.
- Multi-variant scenario design of scientific, technological and socio-economic breakthrough development of fast-growing industrial enterprises of the Russian Federation until 2035 with justification of reference points and bifurcation zones, which helps to adjust the development option taking into account the comparison of resource projection and the projection of development results.
- Compliance-system of management of problems-calls of the industrial enterprises, allowing the companies to resist "the big calls" and to manage the risks inevitably arising at realization of breakthrough development.
- The procedure for the introduction of digital doubles integrated into the platform ecosystem and on their basis digital shadows in key industries as a priority direction of development under conditions of digital transformation that will allow consolidating the participants of industrial markets with the aim of introducing technological innovations.
- The program of digital transformation of industrial enterprises as a set of key initiatives, activities and their results, including the ways of strategic development on the basis of a combination of organizational forms of activity, increased activity, development of integration.
- Methodology for assessing KPI breakthrough development of fast-growing industrial enterprises, which allows you to measure the level of achievement of goals, identify weaknesses, conduct benchmarking at the global level.

- Develop a structure and form an analytical review of the research problem. The analytical review should contain:
 - a. Theme, subject, object, nature, purpose and objectives of the work;
 - b. Systematization of information about the problem under study (key tasks, known positions, theories, premises, etc.) from the standpoint of reliability, doubtfulness, controversy;
 - c. Review of scientific information sources on the subject of the problem under study;
 - d. A description of the methods of performing the work;
 - e. An analytical reference on the results of a review of scientific information sources on the subject of the problem under study, including at least 50 publications from domestic sources and 100 foreign publications, mostly published during the period 2013-2018.
- Identification and justification of digitalization trends for the period up to 2030, a list of end-to-end technologies for the potential for making a technological breakthrough.
- Determination of the rating positions of Russian industrial enterprises at the global level, global benchmarking, identification of best practices and best-in-class solutions.
- Research of fast-developing high-tech companies in Russia. Drawing up a portrait of the company - the national champion on the basis of the analysis of the rating, the identification of fast-growing industrial companies (gazelles).
- 13. Comparison of the contribution of small, medium and large businesses to the growth of the economy in the Russian Federation.
- Identification of drivers and inhibitors of breakthrough development in industrial companies.
- Research of world and Russian experience of development of corporate accelerators.
- Research of the best practices of innovation management in Russian companies.
- Analysis of the market for direct and venture angel investments in industrial companies in Russia.
- Research of behavioral and institutional preconditions of technological development.
- Investigation of the economy as a socio-economic phenomenon.
- Formation of the conceptual foundations for the creation of an enabling environment and a mature ecosystem for the purpose of breakthrough development and technological breakthrough by industrial companies.
- Research of global practices of commercialization of technologies at different stages.
- Development of a methodological approach to assessing the level of scientific and technological development of fast-growing industrial enterprises.
- Development of a methodology for assessing the global competitiveness of fast-growing industrial enterprises.
- Development of a methodological approach to assessing the potential for the formation of multinational Russian-based companies on the basis of fast-growing industrial enterprises.
- Development of the original author's concept of managing fast-growing industrial enterprises for the purposes of breakthrough development and accomplishment of a technological breakthrough, containing classification characteristics and content characteristics.
- Formation of a methodology for managing the breakthrough development of fast-growing industrial enterprises on the basis of laws and development principles, which includes a set of theoretical foundations in terms of hypotheses, applied theories and basic approaches, basic organizational and management mechanisms and basic efficiency assessments.
- Development of a conceptual model and management system for the development of fast-growing industrial enterprises at mega-, macro-, meso- and micro levels.

All the tasks we have solved are solved using digital avatars (Mkrttchian and Aleshina, 2017). Digital Mkrttchian's avatars, more precisely the expert knowledge generated by them, enable each member of the network, called a node, to contain a chain of blocks that makes up the history of transactions performed on the network. Each block contains a set of transactions, the size of which depends on how many banks and financial institutions do not actually have an API, or have a very truncated form. Also, any financial system faces the risk of non-fulfillment or disputing by the parties of the transaction of payments made. Avoid these risks can involve a qualified financial intermediary, which checks the transaction and takes some of the risks. To solve this problem, all kinds of organizations were created: banks, clearing systems, depositories, financial information transfer systems such as Reuters or SWIFT. However, the use of intermediaries leads to a significant increase in the cost and slowdown of calculations. International transactions on time can last up to seven days. In the banking sector, there are obvious serious contradictions between the established traditional business and modern innovative technologies. These contradictions in the very near future cardinally reformat the financial market. And expertise will replace the financial intermediary and create a transaction and transfer it to the network. the transaction message includes information on the public address of the recipient, the transaction value and the digital signature, which proves the authenticity of the transaction. Nodes (computers / users) of the network, after receiving the message, confirm the authenticity and validity of the message by decrypting the digital signature. An authenticated transaction is placed in the "pool" of pending transactions. Nodes (computers / users) of the network, after receiving the message, confirm the authenticity and validity of the message by decrypting the digital signature. An authenticated transaction is placed in the "pool" of pending transactions. The nodes of the network validator receive the proposed block and work on its verification through an iterative process, which requires consensus in most networks. If digital avatars are implemented, they ensure that each transaction is valid and fraudulent transactions are not possible. If all transactions are verified, the new block - the forming expert knowledge is "chained" to the block chain (block box), and the new current status of the registrar is transferred to the network. The entire process can be completed in 3-10 seconds. "

The developed system allows to solve the following tasks based on the use of expert knowledge:

- Assessment of the advantages and disadvantages of the institutional environment, the national economy and the legal system, and preparation of proposals on ways and mechanisms for improvement.
- Substantiation of benchmarks of breakthrough development of dynamic industrial enterprises of medium-sized businesses.
- Development of scenarios for the breakthrough development of fast-growing industrial enterprises. Implementation of the developed scenarios in the practice of dynamic industrial companies of medium business.
- Identification of problems-calls of industrial enterprises. Correction of the list of large calls from the Strategy of scientific and technological development of the Russian Federation.
- Formation of a compliance system for managing problems-calls of industrial enterprises in urban system.
- Carrying out of synergetic modeling of breakthrough scientific and technological development of companies - national champions.
- Formation of the concept of a communication campaign aimed at popularizing innovative activity and promoting success stories.

- Examination of the existing list of publicly accessible information resources for the purpose of breakthrough development of industrial enterprises.
- Development of a methodical approach to the evaluation of the startup cost index and the main characteristics of startups launched.
- Development and validation of the methodology for assessing innovative demand and innovative activity of dynamic medium-sized companies.
- Research of the dynamics of scientific communication in Russia.
- Processing the results of the development of fast-growing industrial enterprises according to the developed scenarios for the first year of observation.
- Development of the procedure for the introduction of digital counterparts and on their basis digital shadows in industrial enterprises.
- Formation of the program of digital transformation of industrial enterprises.
- Development and approbation of KPI evaluation methodology for breakthrough development of fast-growing industrial enterprises. The implementation is planned on the basis of the national champion.
- Modeling the process of creating an industrial-technological enclave as a kind of network structure of the cluster type.

The proposed block system can be successfully applied for Smart solutions in create sustainable urban systems. These solutions provide a massive increase in efficiency for decision-makers. This also provides a new platform for open innovation without permission. The proposed chain of blocks was successful because they did not ask for permission. They were built on an idea in which central authority and supervision should be avoided, and that the network itself must be resistant to all forms of censorship. At the same time, the network time should be open to everyone, and all members should be able to make any transactions that are Smart solutions in create sustainable urban systems. This meant that Mkrttchian's idea of technology was seen as too slow and too risky for Smart Solutions in creating sustainable urban systems. As the digital avatar technology matured, however, more and more people began to see the potential of distributed accounting technology, just in a more controlled setting. If distributed book technology can be adapted to existing laws and regulations, this can lead to the elimination of a large number of costly inefficiencies and replace the basic system for Smart Solutions in create sustainable urban systems.

FUTURE RESEARCH DIRECTIONS

Many developers are rushing to develop software that can use these precedents and act as the best solution provider, often in several markets at the same time. You can imagine the winner scenario - all this because of the effect of a strong network that the largest provider will like, but it's interesting that some signs indicate that this may not be a coincidence. Relying on the technological roots of the blockade created with open source and the ideals of an open network of digital avatars, developers focused their attention on solutions for compatible registers. This means that in the future, the data can be transferred between different registers and allows the trading of assets that are not currently considered commodity. The web of web values will facilitate the trade of all forms of assets, such as currencies, stocks, goods and gold, but this will require completely different digital avatars that will come from the supercomputer. Development of the theory of digital economic security and formation of new knowledge that adequately

describes emerging social threats in the digital economy and gives digital economic security the status of a scientific discipline. Digital economic security is understood by the scientific collective as an information model of synthetic knowledge, whose individual judgments, while within the boundaries of economic and information security, lose their former autonomy and, integrating with social security, become elements of a new system.

The specific fundamental task consists in the initial development of a number of new provisions derived from the theory of economic and information security theory on the basis of the hypothesis that the more the economy is digitized, the higher the level of ensuring its social security requires a person, society and the state. As such provisions the scientific team develops the following:

- The interests of the individual, society, state in the digital economy and the desired characteristics of the object of digital economic security;
- Mechanisms for ensuring digital economic security, based on effective analysis of large data for solving problems of the digital economy, including problem-oriented applied algorithms, machine learning systems and other methods of intellectual analysis;
- Coordination of new designs of digital economic security and showing links between the elements of these structures as part of a more complete system - the digital economy;
- The construction of derivative designs of digital economic security, combining approaches to ensuring the economic, information and social security of the individual, society, the state on the basis of effective analysis of large data for solving problems of the digital economy, including problem-oriented applied algorithms, machine learning systems and other methods of intellectual analysis.

CONCLUSION

- Digital avatars, as a tool of the digital economy, become more and more common. They situate in a new intermediary, located between a buyer and a seller, who seizes and uses virtually unused assets and valuables.
- Convergence with enabled blocking connection allows a seamless peer-to-peer node to exchange assets and cost, reducing the need for trust brokers as intermediaries and increasing the extracted market economic rent in a joint digital economy that.
- Convergence with enabled blocking connection converts the value creation chain. Autonomous robotics, AI, IoT and block systems will digitize logistics and distribution, reducing its importance and therefore increasing the ability of companies at this stage in the value chain to profit.
- Manufacturers can get more value they create, and consumers can pay less. In the long term, technical deflation will fall into the knee of an exponential curve, since most of the production with a 3D print, as well as a virtual and augmented reality, make it cheap for design and give the opportunity to print products at home. And it will also be some kind of new technology, but everything will be determined by economic benefits even then.
- The concept of managing fast-growing industrial enterprises, containing classification features and content characteristics of the development environment; A distinctive feature of the author's approach is the consideration of the environment from the standpoint of the system-synergetic approach as a continuum of framework conditions, including values, institutions, maturity of industries and markets, infrastructure, technology.

- Methodology for managing the breakthrough development of fast-growing industrial enterprises on the basis of laws and development principles, which includes a set of theoretical foundations in terms of hypotheses, applied theories and basic approaches, basic organizational and management mechanisms and basic efficiency assessments.
- Conceptual model and management system for the breakthrough development of fast-growing industrial enterprises, characterized by the allocation as vectors of decomposition of objects, management functions, directions of digitization at mega-, macro-, meso- and microlevels, as well as stages of innovative and production processes that allow achieving achievement global competitiveness, increasing labor productivity in industry and improving the quality of life.
- Methodological approach to the assessment of the level of technological development of industrial enterprises as an integral index with emergent properties, with the allocation of macroeconomic, investment, scientific, technological and innovative, stock, information and communication domains, which gives an idea of the influence of various factors on the change in the final indicator and build predictive estimates.

KEY TERMS AND DEFINITIONS

Application of Blockchain Technology: Is application multifunctional and multilevel information technology designed to reliably record various assets in digital economy to help the technological challenges and created tools.

Avatar Model of High Technology: Is new model with natural intelligent for Avatar introduced in 2011 from Professor Vardan Mkrttchian.

Avatar-Based: Is a new term that describes the planning, search, production, distribution, and delivery of Mkrttchian's digital avatars from the place of origin to consumption.

Blockchain Technology: Is a multifunctional and multilevel information technology, designed to reliably record various assets in digital economy.

Digital Ecosystem: Is an independent group of actors (people, equipment, and organizations) that share the standardized digital platforms to communicate with each other to achieve commercial or social goal.

Expert Knowledge: Is a specific product-expert knowledge, which is created through electronic data distributed on the Internet between business partners and value-added service providers operating in a general digital economy paradigm using blockchain technologies.

Smart Solutions in Create Sustainable Urban System: Means that Mkrttchian's idea of technology was seen as too slow and too risky for Smart Solutions in creating sustainable urban systems. As the digital avatar technology matured, however, more and more people began to see the potential of distributed accounting technology, just in a more controlled setting. If distributed book technology can be adapted to existing laws and regulations, this can lead to the elimination of a large number of costly inefficiencies and replace the basic system for Smart Solutions in create sustainable urban systems.

Supply Chain Management: Is a formal term for managing the physical and information flow of materials and finished products and goods in the supply chain.

Augmenting Organizational Knowledge Management Using Geographic Information Systems

INTRODUCTION

Knowledge is the fundamental factor of production, and knowledge assets within an organization are in knowledge bases, databases, people's heads and filing cabinets (Mohajan, 2017). These assets are supposed to be managed in effective and efficient ways (Faucher, 2010). Organizations must continually rely on decisions, such as deciding on long-term plans, and on tactical schemes to realize middle range ambitions (Sado, 2014). In today's competitive world of business, knowledge management (KM) is of paramount importance for the sustainable development of organizations (Mahdi et al., 2011). Through KM, organizations collect and store potentially important knowledge and manipulate it to realize the utmost effective usage in order to positively change organizational performance (Singh et al., 2006). Through the application of successful KM, organizations can advance their effectiveness and can gain a competitive advantage (Rahimli, 2012). Many firms are realizing that to thrive in complex and dynamic environments, they must be swift and flexible in their day-to-day operations (Bolisani & Bratianu, 2017). Key decisions are now becoming more dependent on understanding and coding complex information acquired from knowledge management systems, and GIS technology has the ability to incorporate this requirement (Satyanarayana et al., 2017). GIS offers a framework for planners to devise things more efficiently (Belsis et al., 2004). GIS is a computing application capable of creating, storing, manipulating, visualizing, analyzing and interpreting geographical data (Gürder & Yılmaz, 2013). GIS shows relationships (of proximity, connectivity, neighbourhood, and overlay), patterns, and trends in the form of maps, reports, and charts (ESRI, 2012). GIS is used for explaining events, predicting outcomes, and planning strategies (ESRI, 2000). Thus, GIS technology guarantees faster decision making (Al-Fareed et al., 2008). It can assist businesses to save time and money while improving access to information and realizing a tangible return on their GIS investment (Klimešová & Vostrovský, 2008).

BACKGROUND

The contemporary beginnings of KM can be traced back to the late 1980s, through to the 1990s (Edwards et al., 2009). The KM concept was first applied in fields, such as information systems, business administration, healthcare, public policy, and library and information sciences (Bennet & Bennet 2008). It is assumed that approximately 80 per cent of data employed in creating information and knowledge in

DOI: 10.4018/978-1-7998-3473-1.ch036

organizations have spatial components (Fitzke & Greve, 2010). Thus, spatial-based information systems can significantly contribute to effective knowledge management activities (Gürder & Yılmaz, 2013). GIS technology can link geographical datasets by use of spatial references through a process known as geocoding (Gürder & Yılmaz, 2013). The spatial reference can be given by coordinates (Nikolli & Idrizi, 2010). Therefore, addresses can be correctly located on a map with the help of the address coordinates (Zandbergen, 2007). According to Strand (2016), “This kind of references allows the observations to be linked by location, providing for new approaches to data collection, new opportunities for data analysis and more use of maps as a visualization and communication tool.” Thus, by applying GIS-functions more information will be generated, information which will allow businesses to conduct analyses, and to carry out new queries and assessments on particular problems (Gürder & Yılmaz, 2013). Non-spatial (attribute) data describe the properties of spatial entities (Gürder & Yılmaz, 2013). The salary and/or age, for example, of a shopper living at a particular address, are attribute data. The address remains a geographical data. A geodatabase warrants that geographical data and attribute data are connected to each other (Gürder & Yılmaz, 2013). The GIS capability to perform spatial analysis can be considered to be the same as the decision capabilities of decision support systems (DSS) (Mennecke, 1996). This enhances their distinguished significance to support basic organizational tasks (Belsis et al., 2004). Thus, spatial-based information systems will contribute to operational knowledge management activities (Gürder & Yılmaz, 2013).

KNOWLEDGE AND KNOWLEDGE MANAGEMENT

Defining Knowledge and Knowledge Management

Knowledge is linked to human actions (Tsoukas & Vladimirou, 2001). It lives in people in terms of information, experiments, perceptiveness and qualifications, products/services, and as activities and processes (Chuang et al., 2013). According to Almashari et al. (2002), knowledge is the ability to act. Wang et al. (2007) defined knowledge as the capability to change information into actions and decisions. In organizations, there are two types of knowledge, namely explicit and tacit knowledge (Nonaka, 1991). Encoded, stored and disseminated data and information are regarded as a content component of the explicit knowledge (Mahmood et al. 2011). Tacit knowledge articulates itself in actions of humans as evaluations, attitudes, competencies, points of view, experiences and skills inside the worldview of an individual (Koskinen et al, 2003). Various definitions of KM exist. Druker (1999) defined knowledge management as “the coordination and exploitation of the cognitive resources of an organisation in order to create the benefit and competitive advantage.” Dalkir et al. (2007) define knowledge management as “Processes and activities which support and facilitate the development and the use of knowledge.” Knowledge management generally entails the planning, organizing, motivating, and controlling of people, processes and systems in an organization to guarantee that its knowledge-related assets are improved and effectively applied so as to attain efficiency, to gain competitive advantage and to guarantee innovation.

Knowledge Management Processes in an Organization

Probst et al. (1997) recognized eight processes in KM in an organization; these processes were regarded as “the building blocks of knowledge management”. Knowledge goals come first, and they pave the way for knowledge management activities. According to Probst et al. (1997), knowledge goals can be

categorized into three classes: *Normative knowledge goals* entail the development of a knowledge-sensitive corporate culture, where distribution and creation of know-how develop the prerequisites for operational knowledge management. *Strategic knowledge goals* outline the principal capabilities of an organization and define its future knowledge needs. *Operational knowledge goals* ascertain that both normative and strategic knowledge goals have largely been implemented as intended and that they are bearing fruit. The second building block is the knowledge generation, and Davenport & Prusak (1997) introduce five modes of knowledge generation. *The acquisition* consists of knowledge into an enterprise from external sources, for example, employing persons with knowledge or hired knowledge from experts. It is regarded by Probst et al. (1997) as the third building block of knowledge management. *Dedicated resources* entail the creation of specific groups, for example, research and development groups, with the aim of identifying and acquiring knowledge. *Fusion* is the creation of new knowledge in business: by drawing together individuals with various points of view, experiences, and skills so as to stimulate new thinking. *Adaptation* can be termed as being open to accommodate recently acquired innovations and also aggressively ready to incorporate new knowledge and skills. *Knowledge networking* involves the sharing of information, formally or otherwise, by people and/or organizations. Knowledge creation, the fourth building block, denotes the continuous bringing together, transfer, and conversion of different kinds of knowledge. Knowledge codification, a process in the creation of knowledge, transforms knowledge into a code that can be understood by people (Mohajan, 2017). Knowledge sharing is the next building block of knowledge management. It is through the sharing of knowledge that individuals and organizations exchange knowledge (Mohajan, 2017). Knowledge application is the use of knowledge for decision-making and executing tasks, and this promotes the overall performance of an organization (Becerra-Fernandez et al., 2004). Knowledge retention is the accumulation and storing of a wealth of knowledge into knowledge database within an agency, it averts loss of the acquired knowledge, and according to Alegbeleye (2010), the ideas of knowledge retention in a database is for easy retrieval of information in the future. The measurement of organizational knowledge constitutes the last building block in the knowledge management process. Knowledge measurement forms an integral part of strategic management (Bolisani & Bratianu, 2018).

ROLE OF KNOWLEDGE MANAGEMENT FOR DEVELOPMENT OF ORGANIZATIONS

According to Payne and Sheen (2004), establishing effective KM in organizations provides a variety of benefits. Epetimehin & Ekundayo (2011) point out that KM effort assist agencies through sharing of valuable organizational insights, lessening redundant work which minimizes company profits, avoiding wastage of time and/or effort in developing something that is already in existence, reducing the time it takes to train employees, retaining intellectual capital as employees' turnover and adjusting to change in environments and markets. This enhances service delivery and preserves knowledge (Dubois & Wilkerson, 2008). According to Mohajan (2017), easy access to accurate information will allow employees to get required information faster. Thus, workers use less time responding to repetitive questions. This will save them time to concentrate on main-and more profitable-work. Employees are prone to doing the same mistakes previously done by others if they are not sharing information (Kayani & Zia 2012). When employees share information, others can have access to it and evaluate that information so as to think carefully before making informed decisions (Siemieniuch & Sinclair, 1999). A major benefit of KM is that information is shared with ease between staff members, and that knowledge is not lost if someone

Figure 1. The Building blocks of knowledge management (modified from Probst et al., 1998 by Gürder & Yilmaz, 2013).

goes on vacation, gets sick, or leaves the company (Martin, 2003). In the era of the knowledge-based economy, businesses must rely more on their knowledge-based resources to thrive (Kim & Gong, 2009) and to cope with the changes.

KNOWLEDGE MANAGEMENT ISSUES AND STRATEGIES

Issues of Knowledge Management

Davenport (1998) highlights the following issues of knowledge management:

- (a) KM is an asset whose effective management requires an investment of other assets.
- (b) In order to achieve effective KM, there is need to have hybrid KM environments since it requires integration of people and technology.
- (c) Since KM is highly political, knowledge managers are required to lobby for the importance and application of knowledge.

- (d) Knowledge will not be well managed unless a group within an enterprise is tasked with the responsibility for KM.
- (e) Organizations should allow the knowledge market to operate, and simply avail and map the knowledge that is really required.
- (f) Knowledge sharing and retrieval should be very simple and straightforward and never be blurred by cryptic interfaces that are not easy to interpret and use.
- (g) People naturally have a tendency of hoarding their knowledge; people should be enticed to shear information by offering them incentives that are too good to ignore.
- (h) Special attention must be dedicated to processes where knowledge is produced, applied and shared.
- (i) Various types of knowledge call for diverse approaches of information engagement.
- (j) Mapping a given knowledge environment should not be unreasonably extensive and time-consuming.
- (k) There should be policies and/or at least some kind of contract between the employee and the enterprise to oversee the preservation and application of knowledge.
- (l) Employees may fear that a newly introduced system will waste their time, or that sharing their knowledge will make them be declared redundant.

Strategies to Govern Efficient and Effective Knowledge Management

Alignment of corporate and knowledge management strategies are the number one success factor in all knowledge management activities (Earl, 2001). This is because strategy:

- (a) Oversees the distribution of money to resources.
- (b) Offers hybrid solutions.
- (c) Is high-order politics.
- (d) Is the point at which knowledge, skills and information offer their optimal value.
- (e) Is vital in setting a vision, architecture and a technology plan to administer developments in intellectual assets and knowledge management processes.
- (f) Is never-ending, for it requires a steady knowledge supply.

These issues underscore the fact that for knowledge to have optimal value, it must be aligned with the future targets of the organization (Tiwana, 2000). An agency must first outline what it is actually doing (and what it is capable of doing), and relate this to what must be done in order to sustain its competitive advantage (Snyman and Kruger, 2004). According to Laudon and Laudon (2004), knowledge management strategies result in the development of information system applications.

GIS AND ORGANIZATIONAL KNOWLEDGE MANAGEMENT

Components of GIS

GIS has wide applicability, and GIS tools are applied by different organizations to access and maintain datasets of spatially related information (Venigalla & Casey, 2006). GIS is a computer system that is able to assemble, store, manipulate and display geographically referenced data and information (Gürder & Yılmaz, 2013). The six major basic components that define the architecture of a GIS are hardware, software, data, methods, network and users (Eldrandaly, 2007).

Figure 2. The Components of a geographic information system

Hardware is the equipment used to support many activities of a GIS. It could be a stand-alone architecture (computer and peripherals) with a central workstation or network-based (client/server) architecture, digitizer, Scanners, GIS receivers, plotters, and printers. *Software* is the application programs that provide the functions and tools needed to store, analyse, and display geographic information. *Methods* are the user-oriented and well defined standard procedures or even software routine, built to help users to efficiently use some GIS functions so that humans can turn that information into knowledge. *Data* is normally stored in a database; spatial data can be kept in a geodatabase while attribute data can be kept, for example, in a relational database. *Users* are the people who could formulate the human problem and analyse geographic information and data, and they range from technical specialists who create and manage the system to those who use it. *Network* refers to both the computer, and social network. Both of these networks assist in the distribution of data. As well, these networks allow for the display of information in the form of web applications, web maps, or even analogue maps using our social network. The GIS system architecture which most of the recent applications is based on enables users to create

Figure 3. Displaying multiple stacked GIS layers (Gabathuler et al., 2012)

and overlap several georeferenced maps on a computer screen, integrating different layers (themes) with different information and data (ESRI, 2012). The enormous amount of applications and services that GIS could cover make this technology a valuable tool for decision support (Adigun & Okubote, 2006).

Spatial Data Formats

GIS uses three formats of data which describe the basic ways on how to represent and store data in the computer; raster, vector, and TIN (Triangulated Irregular Networks) (Adigun & Okubote, 2006). *Vector models* represent geographical features in terms of points, lines and polygons. These models normally represent and store discrete data. They majorly represent features such as rivers, roads, buildings and other solid objects. *Raster* consists of a matrix of cells (or pixels) organized into rows and columns (or a grid) where each cell contains a value representing information. Thus, every single cell has an (x, y) coordinate. The referenced data are stored as pixel values, and this makes it easier to maintain and describe spatial data. The values may be representing elevation above sea level, type of land use, temperature, etc. Raster models are used to represent continuous surfaces or areas. *TIN models* use three coordinates (x, y and z) to represent a particular surface by building a network of triangles, and they are particularly helpful to show DEM (Digital Elevation Models).

Main Functions of GIS in Organizational Knowledge Management

The use of GIS in organizational knowledge management commonly takes place in three phases, namely data entry, data analysis and data presentation (Satyanarayana et al., 2017). Gürder and Yılmaz (2013) outline the main functions of GIS in organizations as follows:

- (a) To process enormous amounts of data.
- (b) To convert them into information.
- (c) To relate them with data belonging to different systems, for example, logistics tracking systems, customer information systems, market analysis systems, order tracking systems, etc.
- (d) To develop knowledge for enterprise strategies, tactical steps, marketing activities, logistics support and sales support.

The major characteristics defining a GIS are its functions for spatial analysis (Satyanarayana et al., 2017). The major objective of spatial data analysis is to transform and combine data from different sources into valuable information. The major spatial analysis functions that are possibly useful for organizational knowledge management are:

- (a) Retrieval functions for selective search and manipulation of data.
- (b) Measurement functions allow measuring distances, lengths or areas.
- (c) Overlay functions allow users to create and overlap several georeferenced maps (with different information and data) on a computer screen, so as to apply the set-theoretic operations of intersection, union, difference, and complement using sets of positions (geometric attribute values) as their arguments.
- (e) Search functions for the retrieval of features falling within a search window (which may be a rectangle, circle, or polygon).
- (f) Proximity (buffer zone generation) functions define an area within a specified distance around a feature (polygons, lines, points, or nodes).
- (g) Connectivity functions accumulate values as they traverse over a feature (s).
- (h) Network analysis is used to compute the shortest path (in terms of distance or travel time) between two points in a network (routing). Alternatively, it finds all points that can be reached within a given distance or duration from a centre (allocation).

Application of GIS in Organizational Knowledge Management

Linking location to information is a process that applies to many aspects of decision making, and for any organization trying to evaluate information, the most intuitive way to view it is on a map, made possible by GIS technology (ESRI, 2012). This is because maps and spatial analysis can reveal patterns, point out problems, and show connections that may not be apparent in tables or text (ESRI, 2012). GIS is a powerful decision support systems that help users in solving complex planning and management issues related to spatially referenced applications (Adigun & Okubote, 2006). A wide range of firms uses GIS for many applications such as selecting a site for a facility, targeting a market segment, and planning a distribution network (Adigun & Okubote, 2006). A truck driver, for example, needs a route of how to most efficiently visit each client. Banking and financial services is now a very competitive business, therefore, financial institutions are applying GIS to help them better understand their data (ESRI, 2012).

Location information is a basic factor in every insurance transaction, and thus insurance companies apply GIS to help build insurance pricing models (ESRI, 2012). GIS has the potential of helping real estate professionals in all segments of their business, from map-based content management to sophisticated investment analysis (Yiorkas & Dimopoulos, 2017). As far as retail services are concerned, using GIS to help to understand what is special about individual locations offers the mechanisms to improve retail operations (Trubint et al., 2006). Libraries, museums, schools, and universities are increasingly using GIS for knowledge management endeavours (Blišťan et al., 2015). Health and human services organizations apply GIS technology to leverage scarce resources and multiply the positive impact of benefits to individuals, families, and society (ESRI, 2012). Natural resource managers rely on the analytical power of GIS to help make critical decisions as they manage the earth's resources (Bussink, 2003). GIS offers public safety personnel the power to maintain and analyse large amounts of location-based information, including files from legacy systems, to visualize spatial interconnectedness and show trends critical to public safety response and planning (ESRI, 2012). Transportation professionals the world over have discovered and embraced GIS as an important tool in managing, planning, evaluating, and maintaining transportation systems (Gupta et al., 2003). GIS in utility and communication companies is a common platform to acquire business data, manage assets, update network information, integrate work orders, acquire customer information, and create reports (ESRI, 2012). Whether it is a non-profit organization, a for-profit corporation, or government, GIS has a special role to play.

GIS Issues and Strategies in Organizational Knowledge Management

The issues of knowledge management associated with the introduction and implementation of technology in an enterprise are often more critical to success than the technological issues (Somers, 1998). For some organizations, GIS may characterize a data and operational framework that affects and ties together most activities of the organization (Somers, 1998). In other organizations, GIS may comprise only of a simple tool applied to perform a particular task (Somers, 1998). The types of GIS implementations differ widely, consisting of diverse technology levels, numbers of users, and has an adverse effect on operational tasks and organizations themselves (Somers, 1998). An organization may employ different operational GIS models at different times which are suitable at different stages of the GIS life cycle (Adigun & Okubote, 2006). A GIS management approach in any organization comprises of proper integration of a GIS organizational model and distinct GIS management strategies (Croswell, 1991). Therefore, the role of GIS and the resultant GIS organization model must then be matched with appropriate GIS management strategies (Adigun & Okubote, 2006).

Application of GIS in the Knowledge Management Processes

Application of GIS in knowledge management can be effected through the knowledge management processes (Gürder & Yılmaz, 2013). Thus, the suitability of GIS in the knowledge management processes is evaluated on the basis of the model the building blocks of knowledge management by Probst et al. (1998). The model consists of six main building blocks of knowledge management, namely generation, acquisition, creation, sharing, application, and retention of knowledge. They form the inner part of the model. The outer part, knowledge goals and knowledge measurement blocks make the model into a management loop. Therefore, the application of GIS in knowledge management is discussed in relation to the six building blocks of knowledge management.

Knowledge Generation

An audit of internal and external organizational knowledge assets precedes any investment endeavours on knowledge management (Gürder & Yılmaz, 2013). Knowledge audit not only assesses what knowledge assets are possessed by a specific organization, but also who produces and use it, how frequent is the knowledge used, and where is the knowledge stored (Lauer & Tanniru, 2001). Thus, organizations should first know their existing internal and external capabilities. In order to do this, GIS offers important contributions (Gürder & Yılmaz, 2013). This contribution can be better understood by the following example: A factory making toys for kids want to design a new product to boost sales. At this instance, very critical questions will crop up, questions concerning the addresses of the targeted customers, their salary range, age, and so on. These questions can satisfactorily be answered after visualizing a map of the data stored in spatial databases of the organization, by use of GIS. By just clicking the right field on the map, one will be able to see the existing information on all customers in that field; information like fields a customer does not exist, the spatial distribution of customers within a particular range of income, and distribution of young families.

Knowledge Acquisition

Presently, technology is advancing very fast, and it can be applied in data acquisition (Cascio & Montealegre, 2016). Social networks and modern information technology systems facilitate communication and exchange of views on different issues among customers, suppliers, and employees (Gürder & Yılmaz, 2013). Thus, the communication process in an organization can be quite effective and efficient if organizations design platforms for corporate GIS. This will enable the organization to gather information on location-related concerns. Therefore, the organization can have a clear view of the unidentified and/or urgent issues, and customer expectations and requirements (Gürder and Yılmaz, 2013). The principle lying behind this concept is the idea that the customers, suppliers, and employees have valuable local information.

Knowledge Creation

GIS is a decision support system, and it enables organizations to transform and integrate spatial data and non-spatial data, to analyze them, and to display the analysis results through maps (Adigun & Okubote, 2006). Considering the example above of a factory producing toys for kids, its aim is to maximize revenue and profit. In its endeavour to target this objective, it aims to make toys for young, highly educated middle-income families. GIS technology will enable the factory to identify places where young, highly educated middle-income families are located. At this point, the enterprise will be knowledgeable about the market where the toys would fetch optimum sales. The map created by the analysis of target regional market comprises knowledge development (Gürder & Yılmaz, 2013). GIS technology is not only for the marketing department, but also for the logistics department through route planning, and for finance department through risk analysis, among other departments within an organization. The chances of developing new knowledge are very high, and especially when GIS is applied in the various departments within an organization (ESRI, 2012).

Knowledge Sharing

Nowadays, social networks and modern information technology systems are very reliable distribution tools (Cascio & Montealegre, 2016). People are no longer interested in reading long messages. They prefer short and straightforward messages. In this kind of communication environment, cartographic images are mostly preferred the same knowledge. Thematic maps as compared to voluminous statistical data allow people to comprehend the issue at a glance. Knowledge and maps created by GIS and archived data can be shared through social networks (Cascio & Montealegre, 2016). It is very possible using GIS to share knowledge assets with internal and external customers who are in need of them (Gürder & Yılmaz, 2013).

Knowledge Application

Geocoding is the process through which spatial data available in GIS are linked with each other through spatial references (Gürder & Yılmaz, 2013). When using GIS-functions, new knowledge can be developed from geographically coded spatial data, since it is very probable to generate new queries, analyses and evaluations by incorporating them again as information into the GIS (Gürder & Yılmaz, 2013). Thus, GIS is able to reuse the “intermediate knowledge” which it develops. Therefore, GIS technology can develop new information and knowledge in the process of its applicability. When GIS is at work, it assists in mashing up outwardly unrelated information, show hidden patterns, mine voluminous datasets, and repetitively applies models (Gürder & Yılmaz, 2013).

Knowledge Retention

Separate knowledge-related activities in organizations are done by different employees in associated departments. More than often, customer representatives are the first point of contact with customers. Also, other employees may come into contact with customers when working in after-sales services. In organizations where the circulation of personnel is high, or where the hierarchical structure is complex, all or part of the knowledge assets might easily be lost (Gürder & Yılmaz, 2013). As well, in the event that some employees resigned, then a considerable amount of valuable knowledge might disappear. This translates into a managerial crisis. A major advantage of the application of GIS technology in an organization is that knowledge assets can be retained and hence they can be inherited from one generation to another (Gürder & Yılmaz, 2013).

ESTABLISHING A GIS MODEL FOR KNOWLEDGE MANAGEMENT IN AN ORGANIZATION

GIS Organizational Models

The starting point in devising a GIS management strategy for an organization is the development of an appropriate organizational model, which establishes the basic character of GIS operations. According to Somer (1998), the appropriate GIS organizational model for any organization is based on its intended role. Other factors include:

- (a) The scope and extent of GIS operations; considering the number of users, applications, and GIS databases and their distribution in the organization.
- (b) The degree of GIS applicability.
- (c) How frequent GIS is used in the organization.
- (d) The complexity of GIS tools; which defines the size of the GIS resources attached to each organizational unit and the entire organization and also determines the sophistication of the operation and the skills and time needed to run GIS.
- (e) The operational structure of the organization; it determines the cost of coordination.

The GIS Implementation Process

GIS implementation involves designing, acquiring, installing, and operationalizing the essential components of data, software, hardware, methods, network, and people to attain GIS needs of an organization (Somers, 1998; Adigun & Okubote, 2006). The traditional process of GIS implementation comprises of a sequence of phases. The first step, project planning, encompasses instituting the scope of the GIS, creating the development team, obtaining the much-needed background information, and developing a preliminary implementation plan (Somers, 1998). The next step, requirements analysis, includes defining the functional and data requirements for the GIS applications and users and evaluating resources, opportunities, and challenges in the organizational and institutional setup (Somers, 1998). The design step necessitates creating a conceptual design for the system, database, applications, and organizational components and approving the design with respect to the requirements analysis results (Adigun & Okubote, 2006). The system acquisition and development phase involves developing software, hardware, and data specifications for system selection and acquisition and data acquisition or (Somers, 1998). Implementation entails installing software, hardware, and databases; developing applications; and carrying out the organizational development needed to support and apply the GIS (Somers, 1998). Finally, the operations and maintenance phase entails integrating GIS into the operating environment of the organization, supporting users, and managing the ongoing process of data and system maintenance (Adigun & Okubote, 2006). Although GIS development steps are generally carried out in sequence, many activities can be done concurrently (Somers, 1998). Other approaches that quicken the process of GIS implementation have many benefits. Provision of immediate products and applications to meet users' current demands, spreading out the expenditure schedule, applying particular expenditures directly to particular benefits, maximizing system utility, and sustaining user and management support are some of the benefits of faster GIS implementation initiative (Somers, 1998; Adigun & Okubote, 2006). Therefore, a variety of alternative approaches to GIS implementation are controlled by cost-benefit issues. What actually drives GIS in the first place is the cost reduction and cost-benefit rationale. GIS technology significantly lowers the time and costs put in certain activities, and data costs can be reduced by minimizing data duplication of data collection, maintenance, and output.

Numerous potential challenges are encountered in the process of deviating away from the standard development process. In their endeavour to implement GIS, the major concern for organizations is to identify which shortcuts are good enough to be taken; what data can be purchased rather than collected, which software can be purchased rather than developed, and which product and service vendors are qualified (Adigun & Okubote, 2006). With a good grasp on the long-term scope, design, and organizational integration of its GIS, organization's many short-term steps can be implemented. In most cases, low-initial-cost alternatives tend to erode the rationale and discipline behind the multipurpose methodology of GIS implementation (Somers, 1998). For alternative approaches to GIS development to succeed,

they must be based on solid planning, analyses, and design. Thus, the implementation approach must be carefully done, so that initial, opportunistic steps contribute to the final design. Flexibility is another key factor in GIS implementation management success since GIS implementation process normally takes a long time. The manager in charge of GIS implementation must be in a position to adjust to constraints and problems that arise and make use of new opportunities (Somers, 1998). Another critical, yet often neglected, factor in GIS implementation is the handling of the transitions between the phases of the development process (Somers, 1998). This can be more challenging and more critical to success than the steps of implementation themselves. Many GIS project managers are able to plan the technical tasks and transitions, but the organizational aspects are often ignored. A technical tool delivered to an organization that has not been adequately equipped can make a technically sound GIS to flop.

SOLUTIONS AND RECOMMENDATIONS

If only businesses build GIS, then they can ease their KM and organizational learning processes, and perform more effective activities both on an individual and collective level. According to Davenport (1998), before any agency can embark on knowledge management activities using GIS, the following should be in place:

- (a) A decision to invest in knowledge management must be taken.
- (b) Knowledge management activities must lead to growth and profitability.
- (c) There is a need for hybrid knowledge management environments due to the technological and human nature of resources.
- (d) There must be high-ranking knowledge champions, people who are familiar with the organization's politics.
- (e) There must be a high-ranking officer knowledgeable in the management function.
- (f) Only knowledge that is of strategic value must be mapped.
- (g) A working knowledge dictionary must be put in place, and it should have the capacity to link technical terms to terms used by knowledge requesters.
- (h) People should be motivated to share knowledge.
- (i) Knowledge work processes should be constantly improved.
- (j) All employees must get involved in knowledge sharing exercises.
- (k) The focus of knowledge management should be on quality, not quantity.
- (l) There should be a knowledge contract between the company and the employees.

Thus, by institutionalizing these issues, organizations will have created an organizational environment favourable for developing knowledge.

FUTURE RESEARCH DIRECTIONS

GIS applications in organizational management are advancing and it is expected that with more research, the GIS architecture will most likely be radically transformed as time progresses. A huge amount of knowledge may result in an unmanageable corpus of data. This could be challenging to the end user due to the technical problems of inserting and retrieving information from a geographical system. Thus, more

research should focus on the development of user-friendly interfaces and applications to close the gap between users and technology. Other problems that deter the integration of GIS into an organization's operation and require more attention include but not limited to lack of basic GIS knowledge, issues of data exchange and interoperability, low access to relevant data in digital format, high data costs and lack of standards, shared concepts and standardized data structures. Steps are required on a cultural as well as on a technical level to achieve seamless integration of GIS technology into the day-to-day habit. Understanding GIS, implementation principles, alternatives, needs of an organization, and how to incorporate these components together, remains the major knowledge management challenge.

CONCLUSION

Without a doubt, knowledge has become a key resource for organizations, as well as individuals. Thus, in order to increase individual and organizational performance, knowledge must be exploited by the use of technological means, and this must be supported with learning techniques to promote its distribution. GIS technology incorporates common database operations, for example, query and statistical analysis which go together with the unique visualization and geographic analysis advantages provided by maps. As well as GIS enables the modelling of spatial networks and offers various tools for the analysis of such networks. The integrated ability of GIS to execute spatial analysis can be thought of as similar to the decision capabilities of decision support systems. Therefore, this characteristic of GIS can contribute significantly to supporting basic organizational tasks.

KEY TERMS AND DEFINITIONS

Database: A structured set of data stored in a computer, managed and maintained for the purpose of easy access to the desired information.

Decision Making: The process of choosing a reasonable alternative from the available options.

Decision Support System (DSS): A computer system that, collects, organizes, and analyzes data so as to promote quality decision-making within an organization.

Digital Elevation Model (DEM): A three-dimensional computer graphics representation of continuous elevation values over a terrain's surface.

Geocoding: The positioning of addresses or spatial objects on the map.

Geographic Information System (GIS): A computer system used in capturing, storing, manipulating, analyzing, managing, and visualizing geographical data.

Organization: A social unit of people that is structured and managed to achieve a particular need or to pursue collective goals.

Triangular Irregular Networks (TIN): They are a digital means to show surface morphology, and are constructed by triangulating a set of vertices.

Data Science for Business Analytics and Business Intelligence

INTRODUCTION

In today's globalized world, companies are no longer competing solely on the basis of the classic production factors such as capital, land and labor. Competitive advantages of an organization are increasingly relying on data or further processed to knowledge (Woodside and Quaddus, 2015). Prominent examples of this shift are the digital players:

- Facebook uses the data to promote advertising campaigns more targeted than any other media company before.
- Amazon collects data from many areas of everyday life such as purchases and products (Amazon Shop), entertainment (Amazon Echo), external services (Amazon WebServices, AWS) and more recently health information (Amazon wants to venture into health services (Isidore, 2018)).

The combination of data results in a variety of application scenarios and new business models (McCallum and Gleason, 2013). They often have the potential to disrupt entire markets (Aluya, 2014). At the same time, many small and specific use cases exist in which companies use innovative methods of data collection and analysis:

- Millions of DNA samples are compared to detect the risk of cancer.
- Virtual agents (e.g., chatbots) can handle the semantics and syntax of input information and develop answers based on documents.

In summary, all of these examples use many digital data sources, process them and open up new information or even knowledge that is digitally available (Williams, 2017). The self-optimizing methods, tools and underlying techniques are typically subsumed under the term "Data Science" (McCallum and Gleason, 2013).

Applications of machine learning with corresponding predictions permeate nearly all areas (examples given with respective companies or institutions) (Siegel, 2013):

- Social (family and personal life): Prediction of future locations from position tracking (Nokia) and prediction of love from online messages (OkCupid).
- Marketing and advertising: Prediction of product choices from past purchases (Tesco) and prediction of cancellations (FedEx).

DOI: 10.4018/978-1-7998-3473-1.ch037

- Financial and insurance: Algorithmic trading (London Stock Exchange) and prediction of loan defaults from past data (Citigroup).
- Healthcare: Prediction of clinical trial recruitment (GSK) and prediction of billing errors (Washington state hospitals).
- Fraud detection: Prediction of tax returns (IRS) and prediction of worker's compensation claims (U.S. Postal Service).
- Fault detection for efficiency and safety: Prediction of oil flow rate via neural networks (National Iranian South Oil Company) and prediction of travel time via traffic analysis (New South Wales, Australia).
- Human resources: Prediction of quitting (Hewlett-Packard) and prediction of job performance from fitness data (U.S. Special Forces).
- Public administration and education: Prediction of student performance (IBM) and prediction of student grading to enable automated grading (Hewlett-Packard).
- Psychology: Prediction of dissatisfaction (Citibank) from the use of certain words.

BACKGROUND

As it might already have become apparent from the introduction, a lot of benefits can be created from the application of data science. But this application requires a somewhat new approach which is connected very much to the idea of agile project management (of data science projects). All the examples given so far are assessed in greater depth by Cao via naming relevant success factors, in particular:

- appropriate thinking approach
- adequate assessment of the complexity of the problem
- adequate modeling
- evaluation of model outcomes
- business engagement.

Furthermore, a distinction between general vs. domain-specific algorithms as well as a distinction between vendor-dependent vs. independent solutions is helpful (chapter 9 of Cao, 2018).

FOCUS OF THE ARTICLE

After specific examples and their background have now been mentioned, this chapter explains stepwise and in much detail how nowadays the challenge of harnessing the abundant amount of existing data is addressed effectively. Thereby it adheres to the usual differentiation between business intelligence and business analytics. For business intelligence it describes in particular the generic process of modern data organization that most data science applications follow, whereas for data analytics it places emphasis on showing that there exist a lot of different approaches which can be used.

SOLUTION AND RECOMMENDATION

In the following, a very detailed outline is given how currently solutions to the data science challenge are found, thereby also pointing out best practices as recommendations.

DEFINITIONS

Modern work is undergoing a shift from an industrial economy that is primarily focused on commercial products towards a knowledge economy in which competitive power results from knowledge-intensive services and processes (Lederer and Riedl, 2018). Today, data is collected in companies from many peripheral devices (e.g., smartphones, scanners in a warehouse, production robots and transportation vehicles), transactions (e.g., EDI orders, online sales, value networks) as well as general business activities (e.g., trade show visits, web research, online reviews, portals). With the ongoing digitization of business results data is available for more and more decision-making situations.

At the same time, concepts and approaches to solve data-driven business situations are often discussed under unsystematic terms. North and Kumta (2014) have described the basic terminology for data and knowledge (see Figure 1) which is widely recognized today.

*Figure 1 The knowledge ladder
(North and Kumta, 2014)*

The bits (0 or 1) of a computer system are systematically linked to characters. Through a syntax (e.g., natural language rules or company codes) data (e.g., the words “UX-2002” or “Smith”) is created. If humans or IT systems can interpret the meaning of the data, this creates information (in the example: the number/name of a customer). Knowing the context of the information (for example, Mr. Smith is currently a B customer), knowledge becomes digitally available for analysis. If meaningful actions are taken (e.g., loyalty programs or cross-selling offers for Mr. Smith) a company makes use of its data-driven possibilities. In this case, a company has taken the steps further up in the knowledge staircase - based on a data analysis, it generated knowledge and applied it meaningfully in the corporate context. When it comes to special competencies, which are unique and valuable (e.g., Netflix collects and interprets the selection as well as in-video behavior like breaks of series to generate new entertainment content), a business case can result from data science applications. All of the concrete steps and techniques of data science involve either top-down (starting with the question which unique selling propositions are to be reached) or bottom-up (analyses based on available data) approaches. The evaluation techniques are often

different and, depending on the application in the company, sometimes very special. In general, data science as an increasing interdisciplinary field of extracting knowledge from data is becoming widespread in many industries (Grover and Kar, 2017). Especially in companies that already use digital workflows for process instances (being situated in branches of industry which heavily rely on data), the application of data science techniques leads to process excellence (Fosso Wamba and Mishra, 2017). Well-founded methods, processes and algorithms as well as supporting systems are already being used in many companies to generate knowledge from data. Various concrete techniques such as artificial neural networks and expert systems are discussed in science and practice (Gallant, 1993). In general, such techniques aim to support a company's strategy, its structures and processes so that lessons learned can be used to improve routine tasks (incremental innovation) or they might even lead to completely new business models (radical or disruptive innovations) (Vyas, 2016). By using data together with digital techniques smarter decisions can be codified and shared between employees, teams and even virtual agents. In a nutshell, with digital data science techniques organizations can create new value and innovation through knowledge (Berman, 2018).

The particular relevance of the topic of data science is reflected by the fact that it is not the pure acquisition of information that is at the center of attraction - due to globalization and the associated rapid growth of digital networks, smart business decisions are facilitated by enormous volume, speed and heterogeneity of data (sometimes discussed under the term "big data"). The main task for many companies, which are trying to improve their processes and business models in a data-driven way, is to use internal as well as external knowledge to make better decisions, thereby trying to increase their learning, adaptability and innovation capacity (Stairs and Reynolds, 2017). In some trend studies it

Figure 2. Generic sources and output types of data science approaches

(Laudon and Laudon 2016; Zolnowski and Böhm, 2013; Jänig, 2011; Botha, Kourie and Snyman 2014)

is predicted that knowledge in the form of assessments, expertise, ratings and recommendations will become a primary resource for successful companies within various branches of industry. This is due to an enormous variety of internal as well as external data which needs to be processed in order to derive intelligent business decisions (Soderborg, 2017). At the same time, many branches of industry are under high pressure through new digital business models (e.g. apps, startups, new platform models and decentralized technologies like the block chain). The intelligent application of data science techniques is currently discussed as a primary way to organize the knowledge resource best, hence allowing for a strategic distinction from the competition (Tapscott and Tapscott, 2016).

Typical data science techniques can be broken down into business intelligence and business analytics methods. Before specific concepts are explained in detail, the overall framework should first be defined (see Figure 2).

Due to the digitization of the economy and society, more and more data sources are available. Most companies internally collect data based on their running business (e.g., transactions, requests). This data may be automatically available in a system (e.g., logs in an Enterprise Resource Planning system) or may be explicitly captured (e.g., manual recording of customer communication history in a Customer Relationship Management system). Since sensors have become much cheaper, especially during this decade, companies tend to gather data in physical assets such as production machines and robots as well. Following the same trend, consumers often quantify themselves (for example with sports apps and other wearables). External data from proprietary providers can be accessed via interfaces for many questions and can thus be included in the internal analysis. At the same time, many organizations and institutions provide freely available data (e.g., open data).

To support business decisions, data science applications help with five fundamental outcomes (Laudon and Laudon 2016; Botha, Kourie and Snyman, 2014):

- **Associations** describe the discovery and quantification of dependencies. A classic example of this output is the basket analysis, which calculates the probability of sales of additional products in online stores. Data science applications that support this output often work with a statistical context analysis.
- **Sequences** evaluate regular historical data and show, for example, trends, cycles and other indirect dependencies. For example, based on the transaction history, the sales of weather-dependent products (e.g., ice cream) may be determined. For this, different forms of regression analyses are typically used.
- A **classification** assigns unclassified objects to already known classes. A typical example is the assignment of persons or companies to existing credit rating scales. Modern approaches for this use a variety of novel internal and external data to arrive at a comprehensive assessment of individuals. In many cases, artificial neural networks can be used to arrive at the classifications.
- **Clustering** describes processes for the building of groups due to similarities. For example, cluster analyses can be used to optimize advertisements because responses (e.g., conversion rates) can lead to an identification of previously unclear relationships (e.g., shared values related to an advertisement message).
- **Forecasts** provide calculations of future values from historical variables. For example, various forms of regression analyses are performed on historical data for prediction. Alternatively, artificial neural networks (with respective weights) can be used for the same purpose.

For considering, for example, the actual (financial) value of companies, many structured data points such as sales, number of employees, locations and products should be taken into account. At the same time, semi- or even unstructured data points such as social media reviews, buying recommendations or test portals results could be used. Going one step further, weak signals such as reviews on employer portals or even new categories of hard facts like production efficiency in a smart factory are nowadays often available for information processing (Viney and Phillips 2015; Fahami et al. 2015; Witkowska, 1999). The salient feature: There are innovative ideas for data usage available that bring new use cases with it. Furthermore, rigid systems and simple database queries need to be rethought in favor of flexible data science knowledge management techniques that make sense of linking internal with external data for good knowledge (Lederer and Riedl, 2018).

PROCESS

The typical process that underlies data science can broadly be organized in acquisition (including storage), preparation and usage (including visualization). Each of these parts may comprise several subparts (see Figure 3).

Figure 3. Data science process steps
(Morgan, 2018; De Mello and Ponti, 2018)

The initial step usually covers **data acquisition** and its respective **storage**. As already described, the number of sources that generate data has increased and still grows rapidly nowadays due to the use of computers in technical labs, scientific fieldwork, surveys in market research and sensors in IoT (Internet of Things) applications (e.g., smart factories). Not only does the number of sources increase, but also the quantity of data they generate does so due to enhanced processing capabilities of modern computers. Storage is done via database management systems that use standards such as SQL (Structured Query Language) (Morgan, 2018; De Mello and Ponti, 2018).

Secondly, we address **data preparation**. As we already mentioned, the typical amount of data that is stored is very large, so it is indispensable to further prepare or transform the raw data to facilitate meaningful analyses and usage procedures. This changes the structure (not the content) of the raw data, which is to a large extent determined by its emitting source. A simple example would be the appropriate alignment of survey data in a spreadsheet to directly facilitate a mixed-linear model analysis by means of a statistics software package. If the number of rows of a spreadsheet grows very large (several millions), this constitutes an incentive to use other means for data handling (data mining tools) as usual

spreadsheet tools (e.g., Microsoft Excel) cannot efficiently handle such amounts of data. Typically, the term “big data” is used, when standard software is not sufficient anymore to cover the intended purpose of data handling. Generally, the data preparation can also (case-dependently) include the step of data cleansing which comprises the filtering of reliable data points and non-observance of questionable values (Morgan, 2018; De Mello and Ponti, 2018).

Thirdly, after an appropriate preparation of the data, the next step covers its usage via **knowledge discovery in databases** (typically comprising modeling, simulation, optimization and prediction methods) together with respective visualization. Usually, the data is used as input for certain (mathematical) models which are implemented in suitable software packages. In the step of data usage most recent developments of “artificial intelligence” have added a lot of value. Very general, artificial intelligence can be defined as automated procedures for goal-oriented conclusions. As learning is a natural precondition for humans to solve problems, machine learning is an essential constituent of artificial intelligence. Within machine learning there is the distinction between supervised and unsupervised learning which differentiates whether training data is provided by human experts or not. Taking this analogy further, it may not be surprising that artificial intelligence is closely modeled with respect to biological standards as artificial neural networks (ANNs) which imitate biological neural nets. Such approaches have been developed since the mid of the twentieth century with “deep learning” via convolutional ANNs constituting the most advanced techniques today. Typically, input data is sent through several layers to “train” the ANN. With help of this training, which results in certain “weights” or, more colloquially, educated guesses, several conclusions can be derived. This approach displays the strength of an automated analysis: not only can large amounts of data be acquired, stored and transformed without human effort, but also sophisticated analyses can be performed after initial setup by humans which then ultimately lead to recommendations and insights that are handed over to humans again. Performing this procedure without the tools for big data analysis would take an enormous and impracticable amount of time (Ross, 2016; Morgan, 2018; De Mello and Ponti, 2018).

As already mentioned, **visualization** is also a major subpart of data usage which covers the creation of charts, plots and other visuals that make the “pure data” more understandable. Everything that can be discovered via such graphical methods can in principle be discovered by algorithms, however sometimes it is desired to provide a better understanding to the end user. This in particular involves a meaningful aggregation or clustering of the data. A simple example would again be a cluster analysis for large amounts of data (Morgan, 2018; De Mello and Ponti, 2018).

CONCEPTS

After describing the environment of data science with possible data sources, generic processes and typical outputs, the exact techniques will now be described. Figure 4 gives an overview of different concepts of data science that are known in the corporate context. As shown, business analytics require more resources and more complex procedures than business intelligence. The possible effects in the form of findings and their analytical validity also differ.

Business Intelligence

Business intelligence brings together such methods that are generally concerned with the collection and interpretation of data in electronic systems. It includes a set of different theories, methods and technolo-

Figure 4. Data science concepts
(Laudon and Laudon, 2016)

gies which transform raw data of different sources into information or knowledge relevant for business decisions. Compared to business analytics methods (see next section), they are more likely to have simple initial data and, in some cases, trivial processing logics (Gossmann and Rinderle-Ma, 2016).

For example, if a company uses a management information system (MIS) that collects data such as sales, transactions and costs, middle managers typically call **ad-hoc or standard queries**. These queries usually correlate (via **statistical procedures**) existing numbers (or numbers that can be calculated from available numbers by using simple operators) and show key performance indicators (e.g., revenue per country or revenue per unit of sales). Intelligence at this level is still predominantly human-based. Data analysts, for example, only develop standard queries to guide operational business. However, many skills are needed for customizing the supporting standard software in order to obtain efficient visualizations (Klein and Gräf, 2017). **Control** and **monitoring** are predominantly used to investigate and observe business processes (recurring instances of the same control flow model) or projects (one-time instances). According to set targets, indicators are measured and constantly monitored. Supporting systems offer these functions in a push or pull approach. Applications of business intelligence mostly make use of the efforts of many companies for general integration. According to Mertens (2015), in addition to data integration (for example, standardization of data formats or central storage of previously fragmented databases) multiple other forms of integration are useful (e.g. integration of functions, methods and processes). Monitoring and control can take place along the value generation of the enterprise if data has been integrated horizontally (e.g., in an Supply Chain Management system). Equally interesting and widely used in the company environment are analyses of vertical integration in which data from the operational level (e.g., business transactions) are, via the middle management (e.g., return from different countries), given to top management (e.g., EBIT calculation) (Haertzen, 2012). **Data mining** is on the threshold of business analytics because, unlike traditional analyses, much of the analysis expertise is transferred to the IT system. Rather than considering top-down issues (e.g., KPIs indicating that the strategic goals of the projects or processes are being achieved), data mining works bottom-up. This means

that it is not the manager or the data analyst who dictates the dimensions or criteria of the analysis (e.g., focus on time, cost or quality), but a system searches for patterns in existing data to achieve business impact and recommends dimensions to consider. As in the methods of business analytics, questions are no longer completely defined by the human user (“Which customers generate the most revenue?”), but the system takes over the direction of the business question (“Which customers should be targeted via a new advertising campaign?”).

Business Analytics

Business analytics, as can already be inferred by its name, considers the use of analytical procedures and methods to generate a value-add for business. It is also often referred to as “Operations Research” and hints at the fact that the methods applied here can also be used in a more broad sense for any type of “operational task”, for example logistics optimization. Business analytics has four major components which are modeling, simulation, optimization and prediction methods.

Appropriate **modeling** is a necessary precondition for simulation, optimization as well as prediction. Summarized in one sentence: a model is an abstract representation of a real-world object or phenomenon in all relevant aspects. Generally, one starts with real-world problems or challenges and tries to make progress on them or solve them via the use of data science. Usually, these real-world problems exhibit many characteristics that may not be relevant for the issue under consideration. That is why a model is built via abstraction: abstraction attempts to reduce things such that only the essential features remain. Hence, models are somehow simplified representations of real-world cases that are better suited for analytical problem solving. Sometimes, several features of a real-world object can be subsumed under a certain aspect for abstraction, but this is highly dependent on the specific situation. It may be that a specific model, although it has already been simplified, is still too complex to handle or solve analytically. Then an even more simplified version is needed. But as one might expect, the more simplified a model is (so-called “toy models”), the more limited are the conclusions that can be drawn from it. Nonetheless, these simple models often help to illuminate important aspects of interest. As models are typically used for computations or simulations, they are formalized via mathematical equations. To give an example: to handle certain problems via “linear programming”, all characterizing features of the model have to be expressed via linear equations. Models typically use the framework of statistics (modeling uncertainty and risk via random variables). There are several types of models which range from blueprints for buildings in architecture to equations for aerodynamic flows in physics. Even business plans can somehow be regarded as models (they take only the numbers into account and do not concentrate on emotional factors like brand, reputation etc.). But the common characteristic of all models that are used for simulation, optimization and prediction methods in physics or business is that they can be meaningfully reduced to certain logical relations. Models are typically labelled by their intended purpose: descriptive models analyze only existing data, predictive models try to predict future quantities and prescriptive models derive insights about certain options for action. Ideally, a good model can be used for all three purposes. Specific simulations using these models lend themselves to optimization and prediction purposes, that is why specific optimization and prediction techniques are usually used synonymously with the respective models (Ragsdale, 2014; Cottle and Mukund, 2017).

Models are then used in **simulations** to allow an investigation of how the real-world object would react or develop under certain conditions (in particular future development).

A typical example of a simulation would be a stress test where a model for the financial stability of a bank is subjected to certain testing conditions like the bursting of a bubble in the stock market. Simula-

tions have several advantages that make them attractive versus real-world experiments. They allow for the cheap testing of new strategies and approaches as costs occur only for computer usage but not for the use of real-world assets. Additionally, simulations are typically completed before some kind of real-world experiment can be fully finished. Therefore, they are helpful to early indicate risks or obstacles that might occur (take again the example of the stress test). The insights that are generated can be used to make more smart decisions and initiate counter-measures if necessary (simulations are often used in risk management). Sometimes simulations also give hints in what aspects a model should be simplified or enhanced. Optimization and prediction methods can be regarded as special instances of a simulation (Ragsdale, 2014; Knopf and Teall, 2015)

In the modeling step, goals are typically formalized via mathematical functions that are to be **optimized**. Optimization describes the process of finding the optimal solution for a certain problem that is characterized by a specific model and a corresponding objective. This means for example maximization of a revenue function or minimization of a cost function. The basic problem underlying optimization topics is rooted in the issue that for decision problems there is usually an exponentially large number of possible solutions (“exponential explosion”) so that raw computation is not a viable solution procedure. Therefore, smart approaches are required to perform an efficient optimization. Very broadly, there is a distinction between linear and non-linear optimization. The former, which can handle any type of problem that can be characterized via (mathematical) linear equations, has achieved widespread fame and is known as “linear programming”. The solution is found via the “simplex algorithm” which exploits geometrical properties of the high-dimensional solution space. An example would be the optimization of logistics (minimizing costs and time) by choosing the shortest subroutes and cleverly distributing the goods that are to be transported. Non-linear optimization, however, addresses all problems that cannot be described analytically via linear equations.

All optimization problems typically involve several constraints that are derived from the real-world cases. But even via sophisticated algorithms and procedures it cannot always be guaranteed that really the best solution is found, that is why “heuristics” are used which somehow represent smart guesses or intuitions. These heuristics also give no guarantee for the best solution, however they often yield better results than the standard algorithms. An example would be the application of statistical techniques to estimate which subparts of the big data set can be disregarded in the analysis. Non-linear optimization techniques together with heuristics constitute an important part of artificial intelligence routines (Ragsdale, 2014; Cottle and Mukund, 2017).

Predictive methods surely constitute the most interesting application of business analytics that can be used in various contexts. Formally, the predictive methods (each based on a specific model) are used to estimate how values of a certain quantity that occur in the future (for example demand for a certain product) differ from the values of the quantity that have been observed in the past (historical data). Prediction methods can be regarded as special cases of optimization methods as predictions are often made via insights that optimally explain past data. As one might expect, the conclusion of a prediction depends on the choice of the predictive method. This choice depends on the particular situation, for example exponential smoothing for short-term forecasts vs. linear regression for long-term forecasts. All methods are characterized by certain parameters that are adjusted via the collected data. Once the parameters have been fixed, the method can be used for specific predictions, for example the development of the Dow Jones. As the predictions will typically not be perfect, the new (differing) data is used for further adjustment of the parameters. This touches the topic of “in-sample risk” vs. “out-of-sample risk”. Reducing the in-sample risk means calibrating the parameters such that historical data is explained as good as possible. But strictly reducing the in-sample risk sometimes leaves more room

for the out-of-sample risk. This is for example the case for the optimal Markowitz portfolio in portfolio theory (which can be viewed as a prediction method for the development of stock prices): here a strict analysis of historical data leads to a concentration on very few assets, but broader distributions have proven to be more robust for future predictions (Meucci, 2009). Typical methods for prediction cover (there are various segmentations to be found in the literature as the topics presented below are intertwined and cannot be delimited clearly): “Exponential smoothing” with a varying number of parameters. The intuition is to “somehow” learn from errors of past predictions (by means of minimizing an error measure like the mean squared deviation). The idea behind “regression techniques” is to suitably fit a smooth relation (sometimes even linear) between the data points for explanation. Regression techniques are typically classified by the number of independent (explaining) variables and dependent (predicted) variables. If more than one independent variable is involved, one talks about “multivariate” regression. If more than one dependent variable is involved, one talks about “multilevel” regression. “Mixed-linear models” (sometimes also called “panel data models”) are a variant of multivariate regression where one independent variable measures time or differences of individuals in a group. Mixed-linear models are typically applied to socio-economic problems.

If instead of a linear relation a more sophisticated relation is used for regression, one talks about “non-linear” regression as then more complicated functions (for example polynomials of higher degree) are used. Furthermore, sometimes special functions are used for handling special types of variables: when it comes to the prediction of binary variables, a widely known example is the “logit regression” (using the logistic function in its model). “Time series” or “stochastic processes” constitute still another class of prediction techniques. Sometimes regression methods are also classified as time series, however we distinguish them as time series are formed by the intuition to explicitly model a following time step by consideration of selected features of its predecessor. The chosen features determine the class of the time series model. The listing below gives an overview of the most important models. Generally, they can be subdivided in discrete and continuous time series (or stochastic processes). Discrete processes consider clearly distinguished time steps, whereas continuous processes try to model processes “without gaps”.

Firstly, we consider discrete processes. When values of previous time steps are considered as input, one labels the process as “auto-regressive” (it can be chosen by parameters how many steps backwards are taken for the input). The opposite would be a “Markov process”: only the (current) starting point is relevant, but not time steps that are located further in the past. Due to their simplicity, Markov processes are widely used. The consideration of the moving average of previous error terms (error between past predictions and observations) is labeled “moving average” prediction. The order of integration characterizes “how far away” a process is from a stationary (“flat”) process. Dependent on the features that are used, one talks about AR, ARMA, or ARIMA processes (AR = auto-regressive, I = Integrated, MA = moving average). Such customized models are then used in the Box-Jenkins approach for prediction. The use of further independent variables to complement an ARIMA process leads to an ARIMAX process.

Secondly, we consider continuous processes which are sometimes also called “diffusion processes” as they originate from attempts to model physical diffusion processes of air molecules. These processes are now used in many different areas, especially in finance (for example calculation of prices for financial options via the Black-Scholes model which resembles a “geometric Brownian motion”). Diffusion processes are also used for heuristics like “simulated annealing” (Hox, 2010; Ragsdale, 2014; Pavliotis 2014; Knopf and Teall, 2015; Shumway and Stoffer, 2017; Morgan 2018).

Machine learning techniques (where learnings are directly applied to make predictions) are usually a combination of the aforementioned optimization and prediction methods. But they also use several new techniques like “decision trees”, “support vector machines” and “multi-layer perceptrons” with convo-

lutional artificial neural networks for deep learning being the latest state-of-the-art method (Ragsdale, 2014; Cao, 2018; Morgan 2018;).

FUTURE RESEARCH DIRECTION

The relatively new discipline of data science is just about to emerge in full force. However, even now several developments are already apparent on the horizon. They are very much the subject of ongoing research and expected to show themselves in the following areas which are supposed to be highly impacted by data science:

- breakthroughs in many fields where there is otherwise stagnating progress (for example in certain science and technology topics)
- disruption of current mechanisms and procedures (business and elsewhere)
- transformation of long practiced approaches (business and elsewhere)
- improvement of innovations.

Hence, data science is supposed to act as an accelerator in many fields. The most effective way of its application is still being searched for (Cao, 2018).

CONCLUSION

As mentioned, data is a somewhat new type of resource that, like every other resource, can be exploited to a varying degree. Great benefits can be created by the application of existing business intelligence / business analytics routines and advanced methods are currently being developed which promise an even more efficient use of data in particular concerning predictive power. The important precondition of having enough data for intelligence and analytics procedures (especially training data for machine learning procedures) is nowadays guaranteed automatically as more and more data is being generated and stored routinely. Surely, some methods are at the moment more successful than others, but one can expect a consequent rise in added value for the application areas mentioned here.

KEY TERMS AND DEFINITIONS

Business Intelligence: Business intelligence includes a set of different theories, methods and technologies which transform raw data of different sources into information or knowledge relevant for business decisions.

Modeling: Modeling is the case-dependent reduction (abstraction) of a real-world problem to its relevant aspects.

Optimization: Optimization describes the process of finding the optimal solution for a certain problem that is characterized by a specific model and a corresponding objective (for example maximization of a quadratic revenue function).

Prediction: Prediction covers the use of historical data and a corresponding model to make conjectures about the future occurrence of a certain event.

Simulation: Simulation describes the (computational) use of a model for testing of its behavior under certain conditions (in particular future development).

Big Data, Data Management, and Business Intelligence

3

Richard T. Herschel

Saint Joseph's University, USA

INTRODUCTION

Big data is one of the most commonly written about topics in today's press. In fact, today it has become a ubiquitous term. It is continuously transforming business, finance, healthcare, medicine, engineering, science, and society itself. Routinely we are provided with new information telling us much more data there is, how much more is now able to be captured, how many new sources it comes from, new ways to process it, and how it can be used in new and novel for decision making. It is a topic that is regularly discussed in boardrooms, business publications, and the mainstream media, because big data provides new insights into everything. Big data encompasses traditional sources of structured transaction data that is now supplemented by mass quantities of unstructured data. This data is processed by new, inexpensive, and faster hardware that is then scrutinized by new and more advanced analytics that provide organizations with more in-depth insight into their operational environment than ever before. And now, role of decision maker is increasingly being assumed by smart machines.

The goal of business intelligence [BI] is to extract value from data to better inform decision making. BI combines text, video, voice, location data, social media, and any other new source of data with traditional data sets in order to learn about, interact with, and predict what is happening so that the organization can respond as fast as possible to whatever it perceives is the opportunity that the data reveals. BI deals with imperfect data that is oftentimes ambiguous, but which is available on a vast scale. As a result, Mayer-Shonberger and Cukier (2014) assert that the effect is that the extraction of value from big data is analogous to a treasure hunt. That is, organizations are scrutinizing big data to learn what is happening, without necessarily needing to understand why. They argue that in a big data world, correlations supersede causality, because the data is simply used to discover patterns and correlations in the data that offer novel and invaluable insights. The more data you have the better the insights. The underlying premise for BI then becomes this: the more data an organization can capture, the better the data-driven probability of understanding what is happening, and the faster you can respond to this insight. This means then that actions taken in BI are often based on an organizational confidence level in the analytic assessment of what the data suggests without the necessity of a clear understanding of the root cause.

Big data would appear to many to be more about systems, and less about people. Certainly, people are important because they are themselves a major source of big data fodder and it is oftentimes people's behavior that big data is trying to affect. Nevertheless, big data also is dependent on people because people must inevitably be responsible for how data is used, how it is managed, and for the consequences of the decisions made when using it.

This paper is intended then to remind us that big data is not simply something that data, systems, and analytics make happen and that we are somehow divorced from it and not responsible for unintended consequences. Instead, prudence would require that since we have unleashed big data, we have to somehow insure to the best of our ability that if we can't control big data, we can at least use com-

DOI: 10.4018/978-1-7998-3473-1.ch038

mon sense in how we approach it and manage it. And, despite new technologies enabling machines to use big data to increasingly make decisions, people will not be able to divorce themselves from their decision-making responsibilities.

BACKGROUND

The amount of data in our world has exploded exponentially such that data, especially unstructured data, is now referred to as “big data”. Where measures of data were once gradually evolving from megabytes to terabytes, the sudden phenomena of big data accelerated these measures to volumes expressed in petabytes (1,024 terabytes) or exabytes (1,024 petabytes). The new influx of data is derived from billions to trillions of records of millions of people—all from different sources (e.g. Web, sales, customer contact center, social media, mobile data and so on). The data is typically loosely structured and often incomplete.

Petrov (2019) states that in 2019, the big data market is expected to grow by 20 percent, with every person generating 1.7 megabytes of data in just a second. By 2020, he claims, there will be approximately 40 trillion gigabytes of data. He notes that 97.2 percent of organizations are investing in big data and artificial intelligence (AI), because automated analytics will become increasingly vital to big data by 2020.

Big Data is the natural result of four major global trends:

1. Mobile computing
2. Social networking
3. Cloud computing
4. Moore’s Law [processing power doubles every 2 years]

A lot of big data is derived from cell phone traffic and social networks, with much of it being stored in the cloud. The amount of this information grows almost exponentially as people routinely interact with companies and each other via wireless and wired networks as a matter of course.

The data being transmitted and captured from these transactions has become a key basis of competition, underpinning new waves of productivity growth, innovation, and consumer surplus, according to research by MGI and McKinsey’s Business Technology Office (Manyika, Chui, Brown, Bughin, Dobbs, Roxburgh, Hung Byers, 2011). From the standpoint of competitiveness and the potential capture of value, big data has had a substantial impact. Today, organizations leverage data-driven strategies to innovate, compete, and capture value from deep and up-to-real-time information. Hence, leaders in every sector are confronted with the need to grapple with the implications of big data in a quest to capture and harness its potential value.

The significance of big data to an organization falls into two categories: analytical use, and enabling new products. Big data analytics can reveal insights hidden previously by data too costly to process, such as peer influence among customers, revealed by analyzing shoppers’ transactions, social and geographical data. Being able to process every item of data in reasonable time removes the troublesome need for sampling and promotes an investigative approach to data, in contrast to the somewhat static nature of running predetermined reports. Hence, big data expands BI’s data-driven decision-making opportunities.

BIG DATA

In their book, “Big Data, Big Analytics: Emerging Business Intelligence and Analytic Trends for Today’s Business”, Minelli, Chambers, and Dhiraj (2013) present significant evidence supporting the value and justification for businesses to be ‘big data-driven’. Minelli et al. define big data as data that goes beyond the traditional limits of data along three dimensions: volume, variety, and velocity. Volume is important because in the past, business use cases and predictive analyses were restricted because the data volume utilized was limited due to storage or computational processing constraints. However, with big data technology removing these constraints and allowing the use of unstructured data and more transaction data for larger data sets, Minelli et al., assert that organizations can now discover more subtle patterns that can lead to targeted actionable decisions, or allow them to factor in more observations or variables captured over a longer period of time into predictive models. Variety of data refers to the different types of data now available for analyses. Instead of simply using structured text or numbers, unstructured text, audio, images, geospatial information, and internet data are now captured and able to be analyzed. Velocity is about the speed at which data is created, accumulated, ingested, and processed. Minelli et al., state that since this data is now readily available, organizations pursue technologies to help them immediately process this information for real-time analytics-based decision-making.

IBM’s Institute for Business Value (2013) added a fourth dimension to describe big data called *veracity*, or the uncertainty of data. They argue that the need to acknowledge and plan for uncertainty is a dimension of big data that has been introduced as executives seek to better understand the world around them. With data types changing constantly, and data collection increasing in quantity and speed, the quality of the data is a concern to be managed.

SAS Institute (2015) proposes two more dimensions as important to the understanding of big data:

1. **Variability.** In addition to the increasing velocities and varieties of data, data flows can be highly inconsistent with periodic peaks. Daily, seasonal and event-triggered peak data loads can be challenging to manage, but they are even more so with unstructured data involved.
2. **Complexity.** Data now comes from multiple sources. And it is still an undertaking to link, match, cleanse and transform data across systems. This requires that organizations increasingly focus on connecting and correlating relationships, hierarchies and multiple data linkages or data can quickly spiral out of control (SAS Institute, 2015).

In essence, big data has now become a new kind of capital. Because of its breadth, volume, richness, and timeliness, many firms see it as an important asset that when harnessed, can be used for creating new products and services. It is a capital on par with financial capital. Oracle (2015) asserts that for CEOs to realize its potential, they must secure access to big data and then increasingly exploit its use before their competition can.

Issues, Controversies, Problems

The rapid rise of the big data phenomena presents a plethora of new challenges for CEOs and their organizations. For example, IDG Enterprise Big Data research (IDG, 2014) conducted a survey with the goal of gaining a better understanding of organizations’ big data initiatives, investments and strategies. Their key finding included the following:

- Organizations are seeing exponential growth in the amount of data managed.
- Companies are intensifying their efforts to derive value through big data initiatives.
- CEOs are focused on the value of big data and are partnering with IT executives who will purchase/manage/execute the strategies.
- Organizations are investing in developing or buying software applications, additional server hardware, and hiring staff with analytics skills for big data initiatives.
- Organizations are facing numerous challenges with big data initiatives, especially the limited availability of skilled employees to analyze and manage data.
- Half of respondents indicated there is no clear thought leader in the big data solution space (IDG, 2014).

Today, big data is getting everyone's attention. That said, many firms are struggling to manage to manage it in order to harness its value.

Some of the challenges they face have been unanticipated. For example, access to mobile data, social media content, and location services information means that businesses are collecting an extensive amount of personal information about their customers. This means that:

- Businesses now have the capacity to leverage more personally identifiable and sensitive information for competitive advantage.
- There is a dramatic surge in identity theft that has the potential to compromise secure transactions.
- Firms must address the development of sophisticated technology to exploit data security vulnerabilities.
- Consumers are increasingly aware and concerned about the collection, use, and disclosure of personal information.
- Legislators are responding to consumer concerns by restricting access to and the use of personal information. Europe's adoption of the General Data Protection Regulation (GDPR) is the best-known example of this. (Palmer, 2018).

An obvious conclusion is that big data can become a liability for organizations if they don't have a demonstrably effective plan to manage it. And, to enable this, firms will not be able to simply rely simply on software solutions, hardware fixes, or other IT initiatives. Instead, management will have to pursue organizational solutions that are designed to insure both data integrity and regulatory compliance.

SOLUTIONS AND RECOMMENDATIONS

To determine how well organizations were taking advantage of big data, the IBM Institute for Business Value (Balboni, Finch, Rodenbeck Reese, & Shockley, 2013) surveyed 900 business and IT executives from 70 countries. Their analysis of the survey results enabled them to establish nine levers that differentiated companies who are best able to derive value from big data from those who were not:

1. *Culture*: Availability and use of data and analytics within an organization
2. *Data*: Structure and formality of the organization's data governance process and the security of its data
3. *Expertise*: Development of and access to data management and analytic skills and capabilities

4. *Funding*: Financial rigor in the analytics funding process
5. *Measurement*: Evaluating the impact on business outcomes
6. *Platform*: Integrated capabilities delivered by hardware and software
7. *Source of value*: Actions and decisions that generate results
8. *Sponsorship*: Executive support and involvement
9. *Trust*: Organizational confidence (Balboni, Finch, Rodenbeck Reese, & Shockley, 2013).

This list affirmed that many of the issues surrounding big data are issues of organizational management. That is, organizational culture, expertise, finance, performance measurement, value creation, leadership, and trust are all traditional management concerns that affect value creation with big data as well.

What surprised management is the tension created from the sheer volume and availability of big data, the new technologies that are being created to acquire and process it, and the stress it is creating for firms to manage and react to it in an effective and timely manner. In essence, big data has become an aggressive, persistent, and pervasive irritant that is able to expose organizational data management limitations. Therefore, one of the easiest ways to understand an organization's shortcomings in the handling of big data would be to examine how capable they currently are in dealing with data management - period.

In his book on data management, Tony Fisher (2009) argues that data governance programs are essential for enterprises to experience success with business intelligence initiatives. As companies grow and look to incorporate additional data sources such as big data it is vital that they have an effective data governance processes in place. To assess this, Fisher created the Data Governance Maturity Model that encompasses four phases: Undisciplined, Reactive, Proactive, and Governed. Each phase represents a different risk versus reward profile and as a company progresses through the model, they increase their ROI for business intelligence while simultaneously reducing risk for the company. Each of these stages is defined below:

- **Undisciplined**: At the initial stage of the Data Governance Maturity Model, an organization has few defined rules and policies regarding data quality and data integration. The same data may exist in multiple applications, and redundant data is often found in different sources, formats and records. Companies in this stage have little or no executive-level insight into the costs of bad or poorly integrated data. About one-third of all organizations are at the Undisciplined stage.
- **Reactive**: A Reactive organization locates and confronts data-centric problems only after they occur. Enterprise resource planning (ERP) or Customer Relationship Management (CRM) applications perform specific tasks, and organizations experience varied levels of data quality. While certain employees understand the importance of high-quality information, corporate management support is lacking. Studies show that the largest share of all organizations – 45 to 50 percent – fall into this stage.
- **Proactive**: Less than 10% of all companies have reached this level. The Proactive organization adopts a more unified enterprise view of data, implementing and using customer data integration and product data management solutions. In this stage, management understands and appreciates the role of data governance and data is seen as a strategic asset. Here data stewards emerge as the primary implementers of data management strategy and work directly with cross-functional teams to enact data quality standards.
- **Governed**: At the Governed stage, an organization has a unified data governance strategy throughout the enterprise. Data quality, data integration and data synchronization are integral parts of all business processes. The organization has a comprehensive program that elevates the process of managing business-critical data (Dataflux, 2015).

These stages provide a framework for organizations to gauge how well they are progressing with their data governance, data quality, and data management efforts while also providing information as to how they can progress to improve to a higher level of Master Data Management [MDM] – a term commonly used in the marketplace to describe this framework. Informatica (2015) defines MDM this way:

Master data management (MDM) in effect turns the Data Governance Maturity Model from a framework to a methodology for improving data management. MDM, like the Maturity Model, has the goal of helping organizations to attain:

- **A single view of the data**—Creating a single, authoritative view of business-critical data from disparate, duplicate, and conflicting information.
- **A 360-degree view of the relationships**—establishing business rules that let firms identify the relationships among the data.
- **A complete view of all interactions**—Integrating the transactions and social interactions that have occurred with a product, customer, channel partner, or other data element to give the organization a complete view of that customer (Informatica, 2015).

Ali (2014) states that organizations who are able to effectively manage their data are better equipped to make time sensitive decisions, monitor emerging trends, react quickly to new business opportunities, and ultimately, maximize the ROI of real-time data better than ever before. If data is being dispersed throughout the enterprise, the ability to discover or to fully leverage analytics tools to gain value and insight from data is cumbersome and inaccurate. Employing an MDM provides a framework for better ensuring that the big data being employed in business intelligence analytics is relevant, timely and accurate. Inevitably then, executive support of MDM should be essential if the organization is going to employ big data for data-driven decision-making.

Eckerson (2014) argues that effective data governance programs must be enterprise-wide with effective programs combining both a top-down and bottom-up approach to data management. He argues that organizations must have a data governance methodology like MDM in place to enable this. Moreover, he recommends that senior management establish a data governance office (DGO) with a full-time staff and a data governance officer. Eckerson proposes that the DGO should work with a data governance steering committee and data stewards to manage and monitor the organization's data governance program. Data stewards are employees with specific subject matter expertise who assume responsibility for certifying data, managing exceptions, and applying controls to safeguard data and individual privacy. Their role is to ensure that the data management, data governance, and business and quality rules definitions are appropriate for different lines of business. Each data steward provides critical input into cross-enterprise data management policies and ensures that these policies are appropriate for the business processes and applications that support the specific lines of business that they represent. Because of the necessity for these interactions, Eckerson believes that data governance is mostly about communications and change management where many conversations are routinely occurring among many people in different parts of the organization to ensure that business processes flow smoothly and efficiently.

Brown, Court, and Willmott (2013) state that effective data management requires executive buy-in for data governance efforts to succeed, because capturing the potential of data analytics requires a clear plan that establishes priorities and well-defined pathways to business results and developing that plan requires leadership. This presumes that executives clearly understand and endorse the use of big data, that they comprehend what data governance is and how important their role is to ensure its adoption and

diffusion, and that they fully comprehend that effective data governance comes at a cost: organizational change. This means that senior management must be intimately involved in crafting the blueprint that encompasses the vision, strategy and requirements for the organization's big data journey. This blueprint should define the scope of big data utilization and management within the organization, prioritize the key business challenges that big data will address, provide a schedule for dealing with these challenges, and provide a plan for developing or acquiring the people and technology resources needed to get the job done (Balboni, Finch, Rodenbeck Reese, & Shockley, 2013).

To be effective, big data solutions must be based on business requirements and address the infrastructure, processes, data sources, and skills required to support this business opportunity. To accomplish this, senior management must establish a plan and process that is consistent with the organization's culture and guiding principles such that these are subsequently reflected in the organizational data governance activities. Management must ensure that data governance is viewed as a continuous and systemic endeavor that is woven into the fabric of the organization's structure and processes.

Executive understanding and support of MDM-type big data governance processes should reflect the conscious realization that they will need to develop, acquire, and retain a strong core of human capital. Qualified data stewards, for example, must be identified and selected. These individuals, through their actions, reflect the values, policies, and procedural requirements that are derived from senior management. In a big data world, executive leadership is also needed to find, develop, and retain strong analytical talent. Analysts with strong mathematical, statistical and computer science roots, as well as familiarity or expertise in areas such as data mining, data visualization, optimization and simulation, text analytics, and predictive analytics are going to be required to harvest meaning and value from big data. The problem is that there is a severe shortage of this talent. Holak (2019) finds that because of big data and artificial intelligence (AI), demand for data science analytical skills is growing exponentially. He provides information showing a 29% increase in demand for data scientists year over year and a 344 percent increase since 2013. Clearly leadership is required to find creative means for acquiring the requisite BI talent that organizations need.

Dyché and Nevala (2015) assert that there are key issues where executives have to be careful in addressing big data and data management issues. These issues include failing to define what data governance is, not approaching big data and data management in a progressive and systematic manner, failing to design data governance teams properly, treating data management as a project, and overlooking organizational cultural issues. They note that issues needing to be addressed by data governance and big data are far-flung and pervasive, ranging from arbitration of cross-functional data usage to information privacy, security, and access policies. As a result, executives need to understand that if they look to implement data governance and other big data initiatives too quickly, the intended results may well be stymied quickly by role confusion, prioritization debates, project development problems, and resistance from the incumbent culture. And with new legislation like the EU's GDPR, executives can ill afford any mistakes or delays.

Whitler (2018) notes that without effective data governance, organizations will be overwhelmed by big data. Indeed, she notes, organizations are suffering from data saturation. The rapid rise in the ability to collect data hasn't been matched by the ability of many organizations to support, filter, and manage this data. Their data management infrastructure and processes are unable to keep up with the continuous deluge of big data. To deal with this issue, she reinforces the importance of effective data governance practices. She asserts that organizations need to:

- focus on identifying and understanding the key questions that you want to employ big data to help you to address,
- identify measures that will address these questions,
- develop a data governance council,
- map out a complete view of the data that identifies what data exists and who has rights to it, and
- identify the business intelligence tools that are best suited to analyzing the data for the issue being addressed.

Partner (2019) warns that the overall importance of data and information within organizations will continue to grow as will the demand for effective data management practices. She reports that there will be more than 20 billion connected sensors by 2020 that will only further aggravate the vast volume of big data. To compound this issue further, she states that organizations must also address the opportunity to take advantage of their other captured, but untapped information assets as well as new opportunities to analyze newly digitized analog assets.

FUTURE RESEARCH DIRECTIONS

Research into the impact of big data needs to expand its focus to explore in more depth how BI is affected by management's ability to cope with data governance, analytics talent recruitment, and other peripheral issues. MDM and data governance activities appear to be sensible techniques for managing data, but it is clear from statistics that not all of these practices are being effectively adopted and deployed. Understanding the rationale for the adoption and leveraging of data management techniques as well as its ability to affect business intelligence and decision making provides meaningful insight into management's competence in exploiting big data.

Managing big data requires common sense. Common sense is derived from thought, intuition, and experience. It incorporates such attributes as the ability to think rationally, to act purposefully, and to deal effectively with your environment. Common sense dictates that firms need to be conscientious with big data so as not to compromise BI efforts and data-driven decision-making. At the same time, however, common sense dictates that there are clear opportunity costs when business intelligence efforts are compromised because of poor big data management practices.

And data management acumen is only going to become more important. Foote (2018) reports that the accessibility of big data has provided a new generation of technology that enables businesses to focus even more on data-driven decision making. Foote believes that the continuous growth of the Internet of Things (IoT) will provide several new resources for big data, including the ability to combine streaming analytics with machine learning and the ability of artificial intelligence (AI) to process big data, thereby improving the efficiency of business intelligence.

CONCLUSION

Big data presents opportunity, but it is inherently filled with noise and uncertainty. It has tremendous potential if people approach it in the right way. It requires effective management, especially competent data management. What it offers is the prospect of gaining better business intelligence for decision making.

Ironically, there is the real potential that people may soon become less involved in business intelligence processes. Ramasamy (2019) predicts that in the next few years artificial intelligence, data analytics, and machine learning embedded in applications will become the primary consumers of data. That is, these technologies will replace people-oriented output such as reports and dashboards, because software will assume the burden of consuming and analyzing data.

This prediction poses the prospect of a fundamental challenge to our understanding about organizational decision making. Traditionally, decision making processes and procedures are assigned to specific individuals. Decisions are made by people. If machines assume these responsibilities, this perspective will necessarily have to shift. Analytics become a surrogate for human reasoning and the machine essentially becomes the decision maker. The problem, however, will be that people will probably remain accountable for the quality of the machine's decisions. In this scenario, it makes sense that one should control what they can control. They should implement effective big data management techniques that ensure data quality and they should employ business intelligence techniques that are grounded in sound reasoning relative to the issue being addressed. Hence, management's role should become one where they necessarily focus on data quality, the appropriateness of the analytics used to gain business intelligence, and the viability of both relative to the resultant decision-making outcomes.

KEY TERMS AND DEFINITIONS

Artificial Intelligence (AI): Is a wide-ranging branch of computer science concerned with building smart machines capable of performing tasks that traditionally required human intelligence.

Big Data: Is a popular term used to describe the exponential growth and availability of data, both structured and unstructured.

Business Intelligence (BI): Is a business management term which refers to applications and technologies which are used to gather, provide access to, and analyze data and information about their company operations.

Data Governance: Is a combination of people, processes and technology that drives high-quality, high-value information. The technology portion of data governance combines data quality, data integration and master data management to ensure that data, processes, and people can be trusted and accountable, and that accurate information flows through the enterprise driving business efficiency.

Data Steward: A data steward is a job role that involves planning, implementing and managing the sourcing, use and maintenance of data assets in an organization. Data stewards enable an organization to take control and govern all the types and forms of data and their associated libraries or repositories.

General Data Protection Regulation (GDPR): Is legislation designed to give European Union citizens more control over their personal data. It dictates laws that organizations must abide by in their acquisition and management of personal information.

Internet of Things (IoT): Refers to the billions of physical devices around the world that are connected to the internet, collecting, and sharing data.

Master Data Management (MDM): Is a technology-enabled discipline in which business and IT work together to ensure the uniformity, accuracy, stewardship, semantic consistency, and accountability of the enterprise's official shared master data assets. Master data is the consistent and uniform set of identifiers and extended attributes that describes the core entities of the enterprise including customers, prospects, citizens, suppliers, sites, hierarchies, and chart of accounts.

Unstructured Data: Unstructured data (or unstructured information) refers to information that either does not have a pre-defined data model or is not organized in a pre-defined manner. Unstructured information is typically text-heavy, but may contain data such as dates, numbers, facts, or video content as well.

Human Face to Data as a Contemporary Approach to Decision Making in the Development Sector

INTRODUCTION

The need to ensure transparency and accountability of development aid has become a global topic of discussion. There is a growing body of literature that looks into the effectiveness and impact of development aid and identifies that many development projects current and past have not met their stated goals (Cronin & Regan, 2002; Wenar, 2006; Leve, 2007; Panday, 2009; Williamson, 2009; Eneh, 2011). In response to such critique, development projects more than ever are faced with the need to incorporate effective, meaningful, and innovative monitoring and evaluation mechanisms to ensure progress is tracked throughout the program cycle (Bamberger, Rao & Woolcock, 2010). On the other hand, it is important to consider that despite having these mechanisms in place, the reliability of the data can still be questioned (Quibria and Islam, 2015). This book chapter offers evidence from a development project in the global south that effectively managed and applied data to inform decision making and therefore enhancing its chances to achieve its goals.

Bangladesh, a South Asian country, joined the global cohort of lower-middle-income countries in 2018 (World Bank, 2019). The country has recorded robust economic growth in recent years, which reached a new peak with about 8.1 percent GDP growth rate in 2018 (Centre for Policy Dialogue, 2019). Since its liberation in 1971, foreign aid has remained crucial to the socio-economic development of this country. Bangladesh received about US\$132,060.6 million of foreign aid (Economic Relations Division, 2019) up to 2017. In 2018, foreign aid accounted for about 16 percent of the national revenue of Bangladesh (Chattopadhyay, 2018). In the 2017-18 fiscal year, the third-highest amount of the external grant (excluding loan) came from the United States and was worth US\$2,796 million (Economic Relations Division, 2019).

Strengthening Household Ability to Respond to Development Opportunities (SHOUHARDO) is a food security program funded by the United States government and the Government of Bangladesh (CARE Bangladesh, 2019a). The program is implemented by an international non-governmental organization, CARE Bangladesh, in eight northern districts of Bangladesh that fall under char (riverine islands) and haor (natural depression) regions (Ibid). Both char and haor are prone to natural disasters, and people suffer from multiple vulnerabilities caused by seasonal flash floods, river, and wave erosion that affect

DOI: 10.4018/978-1-7998-3473-1.ch039

their agriculture, fisheries, livestock, and wage labor livelihoods. The program interventions are geared at addressing livelihood challenges, namely- food insecurity, malnutrition, inadequate public service provision, gender inequality, and disaster-related vulnerabilities for 384,000 ultra-poor people (Ibid).

To achieve its goal, SHOUHARDO III has put significant efforts into ensuring a robust monitoring mechanism (CARE Bangladesh, 2019b). One of the refinement approaches that the program has been using to monitor its results is a longitudinal study. The longitudinal study was designed to track progress on several indicators in 680 randomly selected households that were surveyed every six months. Drawing inference from the quantitative longitudinal study findings was difficult for the program management as some of the trends and changes in some variables were inexplicable; therefore, the program commissioned separate qualitative research to deconstruct and interpret findings from the longitudinal study. The program applied an inductive ethnography to interpret quantitative results by confronting these with data obtained from the qualitative research. The application of this research findings helped the program to make adjustments in the design and implementation.

This chapter begins with the background and methodology for initiating an inductive ethnography and poses descriptive narrative on the findings, and finally, argues that research of this kind can be of significant value if the findings are taken into account while making decisions in the development program. It also delves into implications of this research for program management and puts forth the case of similar research at large scale.

BACKGROUND

Many development projects present their results mostly in the forms of numbers, figures, and graphs. Bamberger, Rao & Woolcock (2010) criticized reporting numbers only as of the result of development projects and referred to this as a partial-approach. One of the ways to go beyond this critique is to conduct rigorous evaluation; however, assessment of that kind usually takes place at the end of a project (Ibid). More recent attention has focused on the provision of mixed-method monitoring as a good practice as it provides real-time feedback and allows the space for development programs to review and adjust project design while it is ongoing (Cronin & Regan, 2002; Ibid).

One of the approaches promoted by the United States Agency for International Development (USAID) and Technical Assistance to NGOs (TANGO) is known as ‘Recurrent Monitoring Survey (RMS)’ which is characterized by real-time and high-frequency panel data collection, and small sample size (Frankenberger, Smith & Griffin, 2017). SHOUHARDO III has been conducting a hybrid RMS called, ‘Fostering Learning and Adaptation in Resilience Building (FLAIRb)’ since July 2017. FLAIRb is designed to track the interplay between the program interventions and household level results; identify activities that are making limited progress and troubleshoot at the household level what the gaps are for appropriate program activities; and, determine resilience progress and identify the areas of refinement in implementation.

After four rounds of the survey, the program sought to review its outcomes at the program and individual household level. The program realized that FLAIRb findings spotted gap areas and progress that can be taken for scaling up within the program and beyond. The quantitative data pieces from FLAIRb were useful, but it did not offer the depth in understanding of the contextual factors and changes at the household level. To address this particular gap, the program conducted small-scale qualitative research, which is the basis of this chapter.

The main objective of this research was to effectively interrogate the data (from the longitudinal research) and build a link between numbers and the people, termed here as ‘human face.’ The program purposively selected eight respondents in haor and char regions, four in each area, and analyzed their responses. A detail explanation of this process is provided in the methodology section.

METHODOLOGY

This research was intended to uncover the meaning of results derived from the longitudinal study. In the process of deconstructing those results, it applied an inductive ethnography and relied on the inductive reasoning process to derive meaning, interpret, and analyze data from another quantitative study (the longitudinal study). Though this research applied an adaptive inductive process to aid an understanding of meaning in complex data (Thomas, 2006), it did not follow the full process of inductive research design as its objective was heavily influenced by another study (Jain & Ogden, 1999; Marshall, 1999).

This research was designed to follow the iterative process in an inductive ethnography that allows the researcher to get back to research locations and subjects to obtain a deeper understanding of contextual factors influencing program implementation (Bamberger et al., 2010). The program explores real-life stories behind the numbers. Both the quantitative longitudinal study and the inductive ethnography have their unique strengths as the quantitative data from the longitudinal study offered an understanding of the magnitude, whereas the qualitative data from the latter provided comprehensive and nuanced perspectives.

The program adopted the extreme sampling technique, which was inspired by Fry, Chantavanich & Chantavanich (1981), who sampled extreme cases from a survey and demographic analysis for an in-depth ethnography (Ibid). In ‘extreme case sampling,’ the researcher purposively selects a sample based on extreme characteristics (Creswell, 2018). For this research the researchers purposively chose a total of eight sample respondents (out of 680 quantitative survey respondents) based on the respondents that had scored the highest absorptive resilience capacity score constructed from eight indicators, which included social capital, access to cash savings, household asset, productive asset, livestock asset, informal safety net, shock preparedness and mitigation, and access to financial institutions.

Before commencing the qualitative research, the program generated individual graphs for each of the eight respondents based on six indicators, including livestock asset, hand washing, income, household dietary diversity, women’s decision making, and resilience capacity. Indicator values in these graphs were derived from all four rounds’ of the longitudinal study. Then, the program developed a semi-structured checklist based on key trends and gaps in those graphs (Rossman and Wilson, 1985). Although the research adopted six variables to synthesize data from the longitudinal study, key themes in the findings narrative were based on unstructured data (Thomas, 2006). Each case is illustrated using ‘thick description’ (detailed contextual information) considering the interwoven parts of qualitative data (Mason, 2002; Skovdal & Cornish, 2015). Of the eight respondents, the researcher chose four diverse cases to portray variation at the individual household level for this chapter, namely that of (i) Salma, (ii) Jakia, (iii) Jarina, and (iv) Monowara from northern Bangladesh.

This research adopted an analysis in which contextual components are documented and reflected (Thorne, 2000). The analysis detected and thematic categories, however, in an unstructured way and included thorough descriptions of socio-economic and cultural factors, program interventions, and other factors that influenced individuals’ lives (Creswell, 2012; Skovdal & Cornish, 2015). The rationale for applying this process was to make a better interpretation of quantitative for the program and to inform decision making at the management level (Fry et al., 1981; Rossman and Wilson, 1985).

FINDINGS

The first case story is about a 25-year old program participant named Zakia, who lives in Malamara village in Jamalpur district. Over the four rounds (between July 2017 and December 2018), there has been an increase in Jakia's resilience capacity. All tracked indicators, except for her livestock assets, showed remarkable improvement.

Salma is a 29-year old woman from Madarer char, also in Jamalpur district. She is one of the participants whose resilience capacity remained stagnant throughout 2017 and 2018. The amount of Salma's loan increased during the fourth round of the study (December 2018) as she underwent an eye operation, which cost US\$ 366. Her dietary diversity, decision-making capacities, and handwashing practices improved.

The third case story focuses on Jarina's household, which seemed to have gradually increased income following an initial fall. Jarina is a 51-year old program participant from Itnakhani village in Habiganj district. Her interview revealed that her livestock assets, household dietary diversity, and handwashing practices progressed notably, even though her income and decision-making capacity remained unstable.

Lastly, Monowara is a 36 years old woman from Horipodo Nagor village in Sunamganj district. Her story shows satisfactory progress in most of the livelihood indicators. Her income, dietary diversity, and handwashing practices improved significantly, as was found in round four. However, Monowara's decision making seemed to decrease during the same period. An on-going court case besides gender-based violence within the household has challenged her otherwise positive livelihood trajectory.

In summary, the four participants could explicitly identify the program's contribution to the changes in their livelihoods. Overall, there have been improvements in areas of income, household decision making, dietary diversity, and handwashing practice. However, each household had unique challenges in pursuit of their livelihoods that affected household incomes such as debts, disease, and health costs. The data collected over the four rounds on each of the women are provided in their respective graphs below. See table 1 for details on how the indicators were developed for each result area.

Table 1. Summary of how indicators were constructed for each result area

Analytics Process Adopted in order to standardize the scale of variables

1. **Livestock asset:** Calculates the current market price of livestock assets (shared or owned) that households had during the survey period. The livestock asset price is reflected in the graph scale as Livestock Assets value US\$122 = 1
2. **Hand Washing:** Six distinct handwashing practices (before food preparation, before eating, before feeding children, after defecation, after cleaning baby's defecation, and after cleaning animal/bird's feces) are considered for critical handwashing behavior. A score of 10 is given when all 6 handwashing practices are used, and the scale in the graphs reflect this.
3. **Income:** Households' monthly income includes both cash income and income from selling household products. The graph is scaled as follows: a monthly household income of US\$12 = 1.
4. **Household Dietary Diversity Score (HDDS):** Household diet diversity includes 12 types of food groups. In the graph, 12 food groups are given a score of 10 and equivalently assigned values.
5. **Women's Economic Empowerment (WEE) Decision Making:** A total of 11 decision areas are considered in household-level decision making for women. If the decision is made by a female respondent or jointly by husband/family members, then the decision-making area is counted. In the graph, a score of 10 is given for all 11 decision areas, and participants' responses are plotted accordingly.
6. **Resilience Capacity Score:** The absorptive capacity indices are constructed from eight indicators: Bonding social capital, Access to cash savings, Household assets, Productive assets, Livestock assets, Informal safety nets (ISN), Shock preparedness and mitigation, and Access to financial institutions. In the graph, a total absorptive Capacity score of 100 is rescaled as 10, and participants' responses are plotted accordingly.

Case One: Zakia

Figure 1 illustrates livelihood outcomes for Zakia, who lived in Malamara village in Jamalpur. In the first round, her resilience capacity initially increased and steadied at the new level over the next three rounds. Zakia's story is a narrative of a woman who was in sixth grade when she got married at aged 14. During the household qualitative interview, she shared that she has two children - one aged 10 years and the other 23 months.

Figure 1. The trend of key variables changes in Zakia's life across the four rounds)

The line graph shows that her livestock holding increased until around three and then declined to the near baseline level. Zakia explained that she had two cows and three goats a year ago, which she sold to buy 0.035 acres of land valued at US\$854. She obtained US\$549 from her livestock sales and added US\$305 from family savings. The source of this family savings was mainly generated from their farming activities, livestock assets, and her husband's non-farm income.

This household stopped agricultural farming two years ago due to their extended family's internal conflicts over land. While the farming activity and livestock assets of this family decreased, the graph shows that their income increased. Zakia's family mostly depended on her husband, a wage laborer, and also a part-time electrical house wiring professional. His monthly income was US\$122. To increase their income, they also planted lumber trees in the newly-purchased land as a long-term investment. On top of that, they invested US\$98 in a rice trade business.

A sharp rise can also be noticed in Zakia's decision making which she confirmed by explaining that she was making more decisions in how as she played a role in ensuring that her family spends within its means. She and her husband made decisions based on joint consultation in most cases, starting from purchasing an asset to her children's education, buying clothes, and buying groceries. Reflecting upon her past, she said her husband's cooperation improved after attending the couple's dialogue sessions. Her husband was a male champion, hence, a promoter of positive male attributes.

The program promoted improved handwashing behavior in the courtyard session, which was further strengthened by household-level counseling. The interview provided additional insight that an improvement in her children's health was a great motivation to adopt better handwashing practices that increased steadily over the last three rounds. She recalled the benefits and said, *I have learned about handwashing from the courtyard sessions and started practicing in my household. I can see the differences between the growths of my two children. My elder son used to fall sick very frequently, but my younger one does not. I also do not have to visit a doctor frequently for my younger son.*

Zakia shared that increasing income had led to positive growth in her household dietary diversity score. Besides, she had a homestead garden where she was growing vegetables, including spinach and red amaranth which was mostly consumed by her family. She fed her children with eggs from the chicken and ducks.

Case Two: Salma

Figure 2 exhibits the changes in livelihood outcomes of Salma, a female program participant household over the four rounds. It shows that her resilience capacity remained mostly stagnant since the second round of the study. Salma's family comprised five members, and she was eight months pregnant during the interview.

Figure 2. The trend of key variables changes in Salma's life across four rounds)

Salma's family income steadily increased from the second round and will most likely keep growing, as her husband took over a salaried job as a security guard with a private company in February 2019 (two months after the quantitative survey was completed). He was earning US\$146 monthly. Previously, her husband worked as a daily wage laborer, and his income was often inadequate for the family. Salma had an eye operation after the third round, which cost them US\$366. US\$244 came from their savings, and they took a loan of US\$122 from *Prodipon* (a local Microfinance Institution). Even though all the savings were spent on the surgery, Salma was confident that in the case of a new crisis or emergency, she could get financial help from her relatives and neighbors, which was indicative of her strong social capital.

Overall, there is a clear upward trend in her decision-making capacity; but this must be understood in the context that her husband lived away from home for work, which allowed her to make decisions on household issues. Sometimes Salma went to the nearest market alone to purchase necessary items, such as dresses for children and groceries. When asked what she would do if any of her children fell sick, she responded, *If any of my children fall sick, I'll take him to a doctor; it does not matter if somebody is accompanying me, or not.* In spite of this confidence, she intimated that the majority of the time, she was accompanied by her brother-in-law, challenging her response on being able to move around alone.

Salma alluded to having a more diverse diet for her household, the pregnancy may have played a role in that, but consistency will be tested as the expected child turns to eat solid food after seven months. The graph also suggests a rising trend for her handwashing behavior that changed from a minimum of three to six critical times. When asked about her handwashing practices, she referred to washing hands before and after eating, before feeding her children, before cooking, after defecation, and after cleaning her child that has defecated. She mentioned learning about this from the courtyard sessions.

The graph shows a declining trend in Salma's livestock during the second round. Her household was affected by a flood in 2017; her family lost two goats and suffered some loss in the rice field. It is noticeable that between July and December 2018, there was little change in her livestock asset. A more recent visit to her household for this qualitative research in April 2019 found that Salma had eight goats and three cows, mostly from shared ownership.

Case Three: Jarina

Figure 3 shows significantly rising trends in several livelihood outcomes for Jarina's household. It suggests that after an initial fall, her resilience capacity gradually increased. Jarina is a 51-year old woman from Itnakhani village in Habiganj district with a family of six – a husband and four children.

From the line graph, it is clear that the livestock assets of Jarina's household grew strikingly over the four rounds. She had only one cow in July 2017, and the number grew to three in December 2018. She spent US\$37, which she received as a monetary input (in 2017) from the program to buy ten hens. The family has consumed some of them and added ducks to the flock from own savings.

Eggs from her chicken alongside the vegetables that she grew in their courtyard, was a major source of nutritious food for this household. She received training from the program on comprehensive homestead development and improved agricultural technologies. She said, *I did not apply Mada (an improved pit technology used in homestead gardening) while growing vegetables previously. From the Farmers Field Business School, I learned improved technology (Mada) and applied in vegetable cultivation, which resulted in better production.* This quotation is in line with the graph, as it shows an upward trajectory in household dietary diversity.

As is illustrated in the graph, their handwashing behavior increased from two critical times per day to four crucial times in between December 2017 and December 2018. During the interview, Jarina could

Figure 3. The trend of key variables changes in Jarina's life across four rounds)

clearly identify critical times of handwashing and some health benefits of such improved behavior (e.g., her children suffered no more from diarrhea, which was fairly common before practicing handwashing; there was a reduction in medicine intake, and the household benefitted monetarily from not having to spend money on medical costs). Observations during the visit to her house revealed that they had a clean toilet with a bar of soap available beside the tube well. She also made a separate shelter for livestock to keep her children away from animal feces, and the shade appeared to be very clean.

Jarina's graph reveals a rather uncommon trend in income levels over the four rounds. With an initial upsurge followed by a fall and then another considerable rise, which indicates a certain level of income instability. During the interview, Jarina indicated that their income was heavily intertwined with seasonality in haor, which is reflected in the graph. The primary source of cash income was her husband's work as a mason both within and outside their locality. During the wet season (June to November), the demand for a mason was higher as the volume construction work increases. He also worked as a sharecropper in the last two years on 0.44 acre of land; they successfully harvested around 0.8 MT rice in year one and 1.6MT in year two. Jarina added to the family income by producing and selling *Chota* (made with cow dung and straws and is used as fuel in villages), rearing livestock, and yielding vegetables. She indicated that the sell spiked up during the rainy season because it was more difficult for people to dry their own *Chota* due to scarce space, leaving them with the only option of buying it.

Jarina's family was saving US\$2.4 every month; however, they used up their savings worth US\$305 being conned by a middleman who promised her husband an overseas job. Further, in November 2017, Jarina's eldest son was wounded by a bamboo stick, which led to surgery at Hobiganj District Hospital, costing them an additional US\$183. Initially, this money was borrowed from Jarina's father, who lived

Figure 4. The trend of key variables changes in Monowara's life across four rounds)

in the same village, but they were able to refund the money within a few days. These shocks severely influenced their family income over the last two years.

The graph shows a somewhat contradictory relation between income and household decision making which can be attributed to Jarina's husband's work pattern. Generally, her husband was the primary buyer of necessary items for the family, but this responsibility fell on Jarina when her husband worked outside their village. Nevertheless, during the interview, Jarina asserted that she and her husband made joint decisions when it came to different family issues.

Case Four: Monowara

Figure 4 illustrates the vital livelihood outcomes of Monowara's household. An overall understanding suggests that her household demonstrated satisfactory progress in most of the indicators. Monowara, a female program participant from Horipodo Nagor village in Sunamganj district, was 36 years old and had a four-year-old son and was six months pregnant during the time of the interview.

One of the notable features in this graph was the upward trajectory of several indicators, including income, household dietary diversity, and handwashing practice. Monowara's family was solely reliant on her husband's income, who was a wage laborer. He worked as a sharecropper during the rice planting seasons (twice a year) and sold stones (collected from the river to construction companies during the monsoon season (from June to November). Between round one and four, their monthly income increased from US\$41 to US\$89. This was largely driven by Monowara and her husband's aspiration to seek alternative livelihoods and acted on available opportunities. The graph showed that her livestock

asset did not increase across the four rounds of the study. It speaks the reality as Monowara owned 18 chicks and five hens, which was not significant in monetary value.

The household's dietary diversity pattern seemed to be correlated with their income. The graph depicts an initial rise and then a fall, followed by a gradual upswing when it comes to this household's nutritional diversity. There was a clear indication that this is directly associated with seasonality (cropping time). In round three, the household dietary diversity score was lower compared to the previous round, as her husband could not work due to his sickness (flu), which negatively affected their food consumption.

Since the second round (December 2017), Monowara's household demonstrated a quick adoption of handwashing practices, which continued through the fourth round. This household settled in a new place in January 2019, as their previous house was falling apart. One of their distant relatives provided a house to four families, including her own as in-kind support.

As the graph presents, Monowara's decision-making capacity began to climb from flat growth in round three, followed by a sharp fall in the next round. This pattern is in line with her narrative, as she was only able to make decisions when her husband was away collecting stones from the river. She mentioned visiting the local market to buy medicine and other daily necessities with her husband's consent. During the interview, it became apparent that gender-based violence was a common phenomenon in their household. Monowara shared that her husband assaulted her for doing anything that he did not approve of.

One other thing the graph could not capture was that her husband was accused of illegal gambling two years ago. To date, the family spent approximately US\$ 1,220 on the court case, requiring them to sell all of their belongings, including furniture and other assets. Monowara and her family not only suffered from financial losses but also lost dignity in their community as a result of her husbands' actions. Monowara said, *Our life would be much better if we did not have to deal with the court case and the cost incurred in this.* This likely hindered their potential growth; however, despite this shock, the family still managed to maintain relatively higher growth in most of their livelihood outcomes.

FUTURE RESEARCH DIRECTIONS: IMPLICATIONS OF THE HUMAN FACE IN DEVELOPMENT PROGRAM

The potential application of data in informed decision making is gradually being realized by policy-makers. This can work as leverage for both government and development organizations to identify need and provide service to the low-income population in a concerted manner (The World Economic Forum, 2012). Insights gained from interrogating data in this way can be leveraged for program management in making informed decisions (Provost and Fawcett, 2013). The key here was to obtain a holistic analysis of the program's evidence and impact in order to boost the overall performance and effectiveness. Tailoring the program's knowledge management strategy to adopt comprehensive data to follow the process of refining and implementation is crucial in this aspect (Kabir & Carayannis, 2013). Findings obtained from this ethnographic research stretched the typical way of interpreting data in the program by offering rich insights from the ground.

Qualitative research in a development program has the potential to give voice to the most marginalized people in a way that they have opportunities for participatory decision making (Skovdal and Cornish, 2016). It is important to ensure that the insights of the community participants' are articulated through the qualitative research influence decision making (Ibid). This research enabled the program to tap into the subjective insights from the respondents, which added to the tacit knowledge base of the program. Tacit knowledge is invaluable for the program as it often dwells in participants' mind and hard to capture

and share which is quite the opposite to the results that come in the form of number and figures from more structured studies and easy to capture, document, and share (Polayni, 1958; Nonaka, 1995; Kabir & Carayannis, 2013). Furthermore, the program is now capable of meaningfully applying tacit knowledge to prioritizing one intervention over another (Skovdal and Cornish, 2016).

SHOUHARDO III intervened in the communities to increase the adoption of improved agricultural technology, ensure participants' income growth, access to health care information and services, household and community awareness on shock preparedness, encourage savings, raise awareness and action to address gender-based violence. Taken together, the results of the longitudinal study suggested significant changes in resilience capacities, women's participation in program groups, and women's decision-making power, and their control over cash income. However, underlying this overall progress, there were areas identified by the ethnography that the program needs to take into account. In this case, SHOUHARDO III will apply knowledge gained from this in three particular areas, including idiosyncratic shocks, women's decision making, and adaptive inquiry methods.

Firstly, each of the respondents from the qualitative research experienced different types of shocks in their day-to-day life, including massive medical costs, losing money in the process of availing better employment opportunities, and court case. The longitudinal study identified the extent of program participants' resilience capacities but could hardly explain why and how changes took place in their lives. The program needs to find strategies to reduce their vulnerabilities from this kind of shock.

The ethnography identified another hidden fact that suggested that women did not necessarily have better decision-making outcomes when more substantial assets were procured. The example given by most women was decision making power over the small purchase, like chickens or ducks, but when it came to cattle, they had to consult with men. The research also revealed that their decision-making capacity was highly influenced by their husbands' seasonal migration. They were more likely to make more decisions during monsoon when husbands were working away from home. The program will require to review its women empowerment interventions to address this issue.

This research required the researcher to adopt an innovating inquiry method. For example, one of the respondents chose not to speak to the researcher in front of her in-laws; therefore, the researcher did the interview in a place that she perceived as safe. This data collection process took into consideration a deeper engagement of the researcher and prioritizing the need and safety of the respondent for ensuring quality as well as accuracy. It is unlikely for a quantitative process to ensure such engagement and gain insights that are required. The program will need to replicate this process at a large scale for future research.

The stories of these four women do not authoritatively represent the entire program. However, their personal stories in relation to the quantitative numbers provide SHOUHARDO III with compelling evidence of the changes in people's lives, issues they must deal with, and areas of limited, unexpected, or negative results that need some program recalibration. These issues will be prioritized in the remaining one year of implementation.

As next steps, a more extensive review will be done in the areas of limited progress to identify coherent actions, while simultaneously ensuring that the excellent progress is being felt across the entire program. This process will focus not only on numbers, figures, and graphs but also in gaining deep insight on social, economic, cultural factors. As SHOUHARDO III moves into the phase-out stage, the purpose of potential future inquiries and analysis will shift from providing information to support adaptive management decisions, to uncover lessons learned about how the implementation strategy helped to enhance resilience capacities, and to assess how the program's close-out strategy will help to sustain the improvements in such capacities

CONCLUSION

There is a positive link between data-driven decision-making and organizational performance. For a development organization, like CARE, it is likely to be associated with the performance of the development programs implemented by it. SHOUHARDO III, as a development program, is still evolving to meaningful capture, share, and use knowledge where needed. This ethnography helped the program to realize that an influential way of generating knowledge can be commissioning need-based research on emerging areas and gaps rather than on structured and overarching agenda (Jones, 2012).

This chapter commenced with the importance of ensuring accountability and effectiveness in development programming. In doing so, it argued that reporting numbers as results are barely useful. It suggested that the program can apply the innovative approach that can address this challenge. Based on the experience of one of the US government and Bangladesh government-funded projects, it showed how a development program could obtain a better and more in-depth understanding of individual lessons at the household level by using a mix of studies including structured and unstructured ones and eventually make adjustment in program design for achieving its goal.

The knowledge generated by the ethnographic research was important for a relatively large project like SHOUHARDO III, which has several focus areas. The program could not detect the gaps that were identified from the qualitative findings earlier through the regular quantitative studies and data analysis. The process explained in this chapter can be expensive as it included a large scale longitudinal study followed by a qualitative one, but it's probably costlier to run a five-year program and end it with no idea on what else could have been done. This chapter concludes with the intention of promoting similar in-depth and rigorous research process and a wide sharing of this practice with other development projects through cross-learning for ensuring the best and effective use of development aid.

KEY TERMS AND DEFINITIONS

Absorptive Capacity: Absorptive capacity is the ability of social systems to absorb and cope with the impacts of climate variability and extremes. The absorptive capacity indices is constructed from eight indicators, which include Bonding social capital, Access to cash savings, Household assets, Productive assets, Livestock assets, Informal safety nets (ISN), Shock preparedness and mitigation and Access to financial institution.

Adaptive Capacity: Adaptive capacity is the ability of social systems to adapt to multiple, long-term, and future climate change risks, and also to learn and adjust after a disaster. The adaptive capacity includes Bridging social capital, Linking social capital, Human capital, Livelihood diversification, Access to financial services, Asset ownership, and Exposure to information.

Char: ‘Char,’ a Bengali term, refers to Mid-channel Island that arises periodically from the river bed due to sediment accretion.

Couple’s Dialogue: Couple dialogue was facilitated at both village and union level, where several couples interact with each other on benefits of improved relationship that leads to nutritional outcome, mutual decision making, and preventing domestic violence.

Courtyard Session: The program disseminated information on dietary diversity, intra-household food equity, Infant and Young Child Feeding (IYCF) counseling focusing on exclusive breastfeeding, promotion of handwashing at critical times, maternal and adolescent nutrition including Iron and Folic Acid (IFA) promotion, separating children from animal feces, hygiene and promotion of sanitation behavior through regular courtyard sessions with pregnant women and lactating mothers.

Farmers’ Field Business School: Farmer Field Business School (FFBS) was an informal platform for local farmers to share knowledge on agricultural production as well as to buy inputs/sell crops collectively.

GDP: Gross domestic product (GDP) represents the monetary value of all final goods and services produced within a nations’ geographic border in a given time.

Haor: Haors are bowl-shaped natural depression lying between the natural banks of rivers or high lands, mostly seen in northeastern Bangladesh.

Idiosyncratic Shocks: Idiosyncratic shocks are a type of shocks that are unique to an individual or family. Loss of jobs, loss of livestock, excessive medical treatment treated under such category of shocks

Longitudinal Study: Longitudinal study is an observational research method that employs continuous or repeated measures to follow particular individuals over prolonged period of time – years or decades.

Male Champion: This refers to men and boys who raised awareness in communities on norms and practices that hinder women’s empowerment.

Recurrent Monitoring Survey (RMS): The regular RMS method is triggered after a shock. FLAIRb was set to be conducted with or without a shock with a bigger time gap in between data collection periods; it was also expanded to include non-traditional indicators such as women empowerment, health, and agricultural practices.

Thick Description: An inherent part of descriptive case study analysis that includes not only describing and observation (usually of human behavior) but also the context in which that behavior occurs.

Transformative Capacity: Transformative capacity requires engagement with issues of power at two levels: changes in the social structures that influence decision-making and changes in individual values, capabilities, and choices.

Data Discovery Systems for Not-for-Profit Organizations

University of Economics in Katowice, Poland

1. INTRODUCTION

Contemporary society is an information society characterized by a high level of technological advancement, where information management, the quality of information and the speed of information transfer are major competitive advantage factors in both industry and service sectors (Hiranya,2017). Modern techniques for information gathering, processing, transfer and utilization are in widespread use. In a society like that, information constitutes a significant part of the added value of most goods and services, and information-intensive activities are pursued by households and citizens alike. Information has joined the classical triad of production factors (Zbroińska,2012), and has been recognized as a dominant resource of contemporary organizations and one of the major drivers of the socio-economic development (Makulska,2017; Toffler,1985). Also, recent years have witnessed a growing interest in the idea of civil society and a rise in the socio-economic potential of the third sector and its role in social services and social capital creation (Edwards,2012). The study is aimed at the not-for-profit organizations which belong to the third sector organizations. Third sector organizations function in a specific way – they are established as a result of social initiative, and are motivated not by a desire to make a profit, but a wish to serve people by satisfying their needs (Defourny,2014). In many respects, however, they are not properly adjusted to the current situation. They are in need of organizational, financial and technological changes in order to fulfil their mission and build their potential effectively. Under existing circumstances organizations are forced to efficiently use data and information in resource management. They have to understand/acknowledge that modern information and communications technologies bring internal benefits and contribute to higher efficiency as well as enhanced quality of the services they provide. The aim of the study is to verify a hypothesis that Data Discovery Systems (DD) are one of the modern technologies which help in achieving these goals, and to present the possibility of using DD systems in effective resource management of not-for-profit organizations. The chapter is structured as follows: Section 1 is an introduction to the subject, based on literature review. Section 2 looks at the characteristics of the third sector organizations (especially not-for-profit organizations) and their operating rules. It also presents Data Discovery systems as a new generation of Business Intelligence systems, which support business analytics, and help in building visualizations and dashboards that show insights for the donor, beneficiary and society. They are self-service IT tools which can be used by employees lacking specialized IT knowledge. Section 3 describes the research methodology. Section 4 discusses the findings of the study on the possibilities of using DD systems in resource management of selected not-for-profit organizations. There is also a presentation of a resource management dashboard designed for Volunteer Fire Departments. The analysis of the data on the physical, human and financial resources proved the DD systems to be the tools that can effectively support efficient¹ resource management in this group of

DOI: 10.4018/978-1-7998-3473-1.ch040

organizations. The chapter concludes with discussion of the research findings, implications and limitations of this research, and avenues for further studies.

2. BACKGROUND

2.1. Characteristics of the Third Sector Organizations

The concept of the division of the socio-economic activity of modern democratic countries assumes the existence of three sectors of the national economy (Defourny,2014; NGO,2017; Palonka,2016):

- the first sector is the state sector, which includes institutions making up the state agencies and offices, i.e. public administration,
- the second sector is the private sector, which comprises institutions and organizations operating for profit, i.e. for-profit entities,
- the third sector is made up of organizations that neither operate for profit nor are part of the state institutional structure, which are social, not economic, in nature, and independent of state, i.e. non-profit entities.

The subject literature review (Evers,Laville,2004; Salamon,Sokolowski,2014) does not allow for clear identification of entities belonging to the third sector because this sector's scope is deeply rooted in the institutional and socio-cultural contexts specific for a particular country or region (Dudzik, Hausner, Izdebski, Kucharski, Laurisz,2008; Skrzypiec,2015).

In Poland, it encompasses, i.a. (Palonka,2018): foundations; associations and their unions; political parties; organizations regulated by separate legal acts, including hunting clubs (Polish Hunting Association), Polish Red Cross, volunteer fire departments, social committees (e.g. social committees for the construction of roads and waterpipe networks); labour unions; employers' organizations, employers' associations; faith-based organizations; groups, such as community clubs, support groups or self-help groups, etc.

In the EU, the third sector is predominantly perceived as the social economy, which comprises both non-profit organizations and social enterprises (GUS,2014; Defourny,2014; Skrzypiec,2015). In broad terms, these organizations can be divided into two categories (Rachunkowość non-profit i not-for-profit,2017):

- non-profit organizations - they must not conduct any economic activity, which results either directly from the legal regulations or the organization's statute, and their assets come from donations, legacies, grants and bequests,
- not-for-profit organizations (NFP) - they can carry economic activity, but all the proceeds generated during its course must serve the organization's statutory goals; the organization's statute should spell out the possibility of conducting economic activity and specify its scope.

The classification indicates that some entities can conduct both statutory and economic activities; the former, however, should not be profit-oriented, while the latter should exclusively serve fulfilling the needs arising from the statute. Organizations operating in the third sector of the national economy (except political parties) can conduct economic activity as long as there are relevant provisions in their statutes. An important point is that not-for-profit entities commencing their economic activity are not

allowed to apply simplified accounting methods, but have to fully comply with the requirements of the Accounting Act. Thus, it is advisable for them to keep separate records of the statutory and economic activities. Also, they have to set out the rules for the division of the administrative expenses into expenses related to the statutory activities and those related to the economic activity (Cebrowska,2010).

In Poland, organizations of the third sector of the national economy operate across sectors (Klon-Jawor,2015), and consequently experience a variety of management problems. There are diverse causal factors behind them, including financing methods, ensuring physical resources, fundraising and financial settlement, securing funding or equipment indispensable for running/supporting the organization's operations, excessive or complicated formalities regarding the use of funds obtained from donors, sponsors or the European Union funding programmes, varied physical facilities, or personnel capabilities of the organization (Klon-Jawor,2015). The organizations' leaders have to ensure that they operate in compliance with the civil, accounting, labour, etc. law. They are obliged to effectively manage the organizations' resources (tangible and intangible), administer their operations, settle projects, and discharge financial liabilities. They make major decisions in the organization, represent it (e.g. contacts with administration officials, sponsors, media, etc.), raise money for the organization and manage its funds (Klon-Jawor,2015).

Today, not-for-profit organizations are working in an era of heightened scrutiny, greater demands, fewer resources, and increased competition. They have to understand how data and information can best serve their purpose. The deployment of modern IT tools for analysis should allow not-for-profits to utilize data and information for internal efficiency gains and better service delivery.

2.2. Classic Business Intelligence Systems

Competition, globalization, and information and communications technologies change the rules for the functioning and management of contemporary organizations (Pomykalski,2017), and force organizations to acquire or develop skills in optimizing their resources and resource utilization in almost every aspect of their work (Griffin,2017). As a result, it is extremely difficult for organizations to solve a problem, and next – to choose the best operational variant unless they possess data and information on their resources, markets, clients, strengths and weaknesses, and the potential conditions for future activity. They also need information that allows skillful coordination of managerial activities in all functional areas, i.e. the management of fixed assets, finance, human resources, production and service provision processes, supply chain and distribution logistics, sales, and customer relations (Walczak,2012). Due to the abundance and diversity of the available data, the organization's activity in this sphere has to be supported by ICT solutions. The software market offers a variety of information systems that can assist in the management of all kinds of organizations (Decyzje,2018). These are often tools with a wide range of functionalities which enable the management of different organization resources and support decision-making in different areas. Research shows that both public sector organizations (GUS,2015) and private sector organizations (GUS,2016) commonly adopt these solutions, while not-for-profits make poor use of ICT and information systems (IS) to support their operations and management (GUS,2014; Palonka, Begovic,2016). The reasons for this limited utilization still remain unexplained. It can be noticed, however, that changes in the conditions under which these organizations operate necessitate the implementation of IS, or the restructuring and expansion of the existing IS and the adaptation of the existing information and communications architecture. This kind of investment is both costly and time-consuming, it requires a massive financial outlay (Computerworld,2015; Iwaniuk,2011) as well as personnel's up-to-date knowledge of ICT and IS and relevant skills (Computerworld,2015).

For many years organizations have been using Business Intelligence systems to support management processes. The systems assist in the analysis of a decision situation and provide users with information indispensable for conducting activity and making business decisions. They are an information platform enabling analysis of the data stored in databases. They can be employed in various domain areas, and the analyzed data can describe both internal and external processes. They can be used to assess the current state of processes and to predict significant phenomena (Bojar, Rostek, Knopik, 2014). Modern managers, however, demand easy-to-use tools to simulate events by means of the “what-if ” analysis, predict trends and make forecasts. These are complex tasks as one has to „know” the dependencies between the variables describing the organization’s structure and the processes taking place within the organization and in its environment. Users, on the other hand, would like to have a support system that would be automated, simple and that would not require hiring a specialist (an analyst or an IT specialist) (GUS, 2014; Computerworld, 2015).

There are some core platform attributes to consider when selecting a modern BI platform (Sadiq, 2013; Yeoh, Koronios, 2010):

- Platform integration and accessibility
 - Can all of the steps of the modern analytics workflow be executed seamlessly within the platform without the need to move between modules/products in a disconnected manner?
 - Can all of the steps of the modern analytics workflow be executed without IT involvement or specialized skills?
- Ease of use
 - Is it easy for BI platform administrators to install, configure, and manage the platform?
 - Is it easy for content creators to prepare data and curate data sources without upfront or on-going assistance from IT?
 - Is it easy for content creators to author content and access the analytic capabilities of the platform without upfront or ongoing assistance from IT?
 - Is it easy for non-technical content consumers to find, view and interact with available analytic content?
 - Is it easy for non-technical content consumers to ask deeper questions autonomously and customize existing published content to suit their specific needs?
- User enablement
 - Is role-specific training available and accessible to all users?
 - Are there self-paced tutorials and/or online webinars that users can access?
 - Is it easy for users to search and find answers to product-specific questions?
 - Is there a robust and active user community accessible to share and learn best practices, tips & tricks, etc.?
 - What is the platform vendor’s reputation for resolving technical support issues?
 - Are professional services (through vendor or partners) readily available?
 - What is the platform vendor’s reputation for ensuring customer success and ongoing engagement with customers?
- Deployment flexibility
 - Does the platform offer flexible deployment options (e.g. SaaS, public/private cloud deployment, on-premises, etc.)?
 - Does the platform offer flexible data storage options (e.g. in-DB vs. platform storage (in-memory))?

- Does the platform support hybrid connectivity of on-premises and cloud data sources?
- Is the platform scalable to accommodate increasing data volumes and additional users over time?
- Can the platform easily scale up and out depending on the needs of the organization?
- Pricing and packaging
 - Is the product packaging easy to understand?
 - Are the available licensing options clear and transparent?
 - Do the licensing options offer the right features and value for the price?
 - Is the pricing model for the platform easy to understand?
 - Is the pricing model for the platform flexible and scalable?

Analysis of BI platform attributes directs attention to modern BI systems. In recent years organizations begin the transition from a traditional top-down approach driven by IT to one based on self-service. The traditional approach to BI is becoming less and less relevant as the business demands the agility that comes with self-service to drive adoption and improve organization outcomes. This, paired with the continued exponential growth in data volume and complexity, presents IT with an important choice. The Data Discovery approach is becoming popular because DD systems are able to meet the information requirements of managers in the current socio-economic environment. The chapter attempts to present the possibilities of using Data Discovery Systems in not-for-profit organizations.

2.3. Data Discovery Systems as a Modern Business Intelligence System

One of the directions that modern management support information systems evolve in is the development of modules which enable users (managers, leaders) to utilize the collected information/data on their own, without the help of IT specialists. This kind of solutions are called Data Discovery or Business Discovery, i.e. self-service Business Intelligence (Waszczuk,2014). The aim of self-service is to facilitate access to source data for reporting and analysis, and to provide easier and enhanced access to data analysis features through simpler, configurable and collaborative end-users' interfaces. Since DD systems use technologies that allow large volumes of information to be processed fast, their analytics features are part of the visualization layer. Users have the possibility and powers to satisfy their information needs *ad hoc*, by single-handedly generating reports, formulating queries and performing analyses due to the access to multi-dimensional and multi-directional data exploration. There is no necessity to create views, use OLAP cubes or data warehouse beforehand (they can, however, be a source of the data). Users can also configure the appearance of the executive dashboards so that they meet their preferences (Waszczuk,2014). The self-service BI systems differ from the classic BI systems in several respects (Blitz,2017); they (Łada, Burnet-Wyrwa,2015):

- put business requirements of an organization and user value, not the information system, first;
- offer greater possibilities for the introduction of changes to the organization and improvement of its outcomes based on the analysis, integration, transformation and interpretation of data from multiple external and internal sources;
- enable managers to make decisions based on the information from the reports that they have generated themselves, using data which has been transformed, supplemented with additional measures and dimensions, and appropriately presented;

- track programs monitoring organizational changes, in various views on managerial dashboards individually configured by the users;
- allow data to be updated in real time, which results in instant modelling of relationships, measures, hierarchies and indicators;
- promote active selection of a wide variety of data, to be analysed from various perspectives, instead of storing fixed datasets;
- facilitate information sharing and collaboration of managerial teams and analysts, as well as offer opportunities for exchange of ideas and joint creation of new solutions for the organization;
- „bring data to life” by means of interactive graph analytics, i.e. data visualization and presentation, leading to the discovery of the hidden relationships between data items.

The users of self-service BI systems can perform complex analytics tasks even if they lack strong analytical skills or knowledge of programming languages, or they do not engage software developers familiar with SQL. All the users in a given organization can create personalized insights that meet their unique information needs (Datatechnology,2017), and the data sorted this way can be accessed by and shared with other members of the organization. The solutions are built on an open platform, which enables integration of social media data and business data. The systems can provide live data and analyses, so users can respond to each situation/query no matter what mobile devices they use at a particular moment (Qlikview,2018). Taking into consideration these attributes of the DD systems, it can be stated that they satisfy the demands of the managers of modern organizations (including not-for-profits). However, using them in organizations requires a new framework and overall strategy. This means that past decisions supporting the core foundational components of a BI system (people, process, and platform) must be revisited (Yeoh, Koronios,2010):

- **People** – a successful transition to self-service business analytics begins with people. A BI model that embraces self-service puts business users and analysts first and allows them to explore, discover, and build content that they will ultimately use to make better business decisions and transform business processes. Collaboration between the business and IT is critical to the success of the implementation as IT knows how to manage data and the business knows how to interpret and use data within the business processes they support. They have the context within which analytics and the insight derived from it will be used to make better business decisions and ultimately improve outcomes. This collaboration of the groups early on will lead to the deployment of a platform that meets the needs of the business.
- **Process** – a modern analytics solution requires new processes and newly-defined organizational roles and responsibilities to truly enable a collaborative self-service-based development process. Modern BI requires updated processes to support self-service analytics across the organization. It also requires the definition of new success metrics that IT and the business are jointly accountable for.
- **Platform** – a modern platform must address a wide range of needs and different personas as well as the increased pace of business and the exponential growth in data volume and complexity. IT requires that the chosen platform enables governance and security while end users require easy access to content and the ability to explore and discovery in a safe environment. The chosen platform must also be able to evolve with the landscape and integrate easily with other systems within an organization. The most critical aspect is the ability to meet these diverse needs in an integrated

and intuitive way without having to introduce separate products or modules to execute specific tasks throughout the process.

Leaders of not-for-profit organizations should capitalize on this market shift and seize the opportunity to redefine the role of BI and analytics as a far more strategic one, critical to the future success of the organization. However, the selection of an appropriate system may prove difficult due to great functional and technological differences between the solutions available in the market. The Gartner report evaluating Business Intelligence and analytics platforms recognizes Qlik, Tableau and Microsoft as leaders (Coughlan,2018). In 2018, Tableau was rated among the top solutions for the sixth straight year. Compared to the competitors, it still offers the broadest range of functionalities and the most attractive pricing model. This explains why Tableau was chosen to conduct the study verifying the research hypothesis..

3. SOLUTIONS AND RECOMMENDATIONS

The aim of this chapter is to present the possibility of using DD systems in effective resource management of not-for-profit organizations based on the case study of a selected organization. The work towards the goal involved forming a research hypothesis and then an attempt In the pursuit of the goal, a research hypothesis was formed and then an effort was made to verify it in the course of a study which followed a research procedure developed by the author.

3.1. Research Hypothesis

The research hypothesis to be verified was:

Data Discovery Systems bring not-for-profits internal benefits, contribute to higher resource efficiency as well as enhanced quality of the services provided by these organizations.

3.2. Research Procedure

Research methods included a critical review of literature, documentation review, analysis and synthesis, statistical analysis, induction and deduction, case study.

The following steps were taken in the research project on the possibility of using Data Discovery systems for resource management in not-for-profit organizations:

1. Pertinent literature was reviewed and the characteristics specific to the functioning of the organizations belonging to the third sector of the national economy, particularly not-for-profit organizations, were identified and described.
2. The research object – the Volunteer Fire Department (OSP) operating in Wyszaków district in Mazowieckie province was selected. The research data was extracted from the activity report and financial statement of the Volunteer Fire Department in Zabrodzie for the year 2015 (Zabrodzie,2017).
3. The users of the executive dashboard that was to be designed – the Board of the OSP in Zawodzie – were identified, and their expectations and information needs were defined.
4. The data was organized and entered into an MS Excel spreadsheet database – the dimensions and measures necessary for the analysis were established and calculated.

5. The analysis and visualization of the collected data were performed by means of the Data Discovery system – Tableau 2018.3 (Hi5data,2017).

3.3. Research Findings

The study led to the development of a resource management dashboard in the Data Discovery system – Tableau 2018.3. The dashboard consists of three parts:

- part one includes information about the activities of the Volunteer Fire Department in Zabrodzie against a backdrop of the other Volunteer Fire Departments operating in particular communes of Wyszaków district (Figure 1.);
- part two presents data regarding the personnel resources of the Volunteer Fire Department in Zabrodzie;
- part three comprises information on the revenues and expenditures, and their breakdown, of the Volunteer Fire Department in Zabrodzie for the year 2015.

Figure 1. Action report data – Volunteer Fire Department calls in 2015

Source: own elaboration

Data was visualized as: horizontal bars, pie bars, symbol maps, treemaps, etc., depending on the selected dimensions and measures.

The analysis of the dashboard data enables fulfilling the users' information needs by providing information on:

- the incidents, and the frequency of the incidents, occurring in the towns and villages located in the district,

- the most/the least common incidents happening in the towns, villages and communes of the district,
- the number of particular incidents where particular Volunteer Fire Departments intervened expressed as a percentage of the total number of incidents occurring in the district,
- the lacking equipment and gear needed for the most common incidents,
- the time spent by firefighters on rescue operations,
- the dynamics of the membership increase (active, honorary and supporting members),
- the increase in the firefighters' competence,
- the amount of remunerations paid to the firefighters for their participation in rescue operations from the Commune's budget,
- the amount of the Volunteer Fire Department's revenues and expenditures and their breakdown.

The information enables managers to efficiently manage the organization by optimizing the utilization of the resources it has at its disposal. They can make operational and strategic decisions regarding, for example:

- the development of the firefighters' competencies by their participation in refresher courses and training adapted to the requirements of the most common rescue operations,
- the purchase of the equipment and gear the organization lacks,
- an increase in the receipts obtained from, e.g. the Provincial Fund for Environmental Protection and Water Management, or in business revenue,
- the management of the firefighters' working time;
- expenditure control, etc.

Summing up, the validation of the dashboard showed that its information content satisfies the demands of a not-for-profit's managers. The results of the research confirm the hypothesis that Data Discovery Systems bring not-for-profit organizations internal benefits, contribute to higher resource efficiency as well as enhanced quality of the services provided by these organizations. However, in order to achieve maximum efficiency, it is necessary to obtain more detailed data on the operational activities of the Volunteer Fire Department in Zabrodzie and other volunteer fire departments from Wyszaków district. Consequently, the organization will gain access to coherent and comprehensive information on what is happening. The dashboard user can single-handedly perform analyses and create visualizations in accordance with his/her current needs and make them available to other interested parties no matter where they are and what device they use. Detailed data collected in the data source (e.g. MS Excel, MS Access), text files (.csv, .pdf), or files from web analytics platform (Google Analytics, etc.) can be accessed any time. The cost of Tableau implementation is lower than the cost of a classic Business Intelligence system (Tableau, 2018). Moreover, the organization does not need expert IT knowledge or the latest computer set (a Windows 7 operating system will suffice) to use this software.

4. FUTURE RESEARCH DIRECTIONS

Recently, we have witnessed extreme technological advancement, which determines the daily functioning of society in various spheres of its activity as well as that of organizations, no matter what their size and industry they operate in are. There has been a growing interest in the civil society. New business needs

have arisen and new processes have occurred, whose implementation requires access to data obtained from various sources. Data analytics and visualization systems, Big Data, mobility and cloud computing – these are business technologies and models that affect and determine the direction for the ICT development. Encyclopedia of Organizational Knowledge, Administration, and Technologies, 1st Edition, will be comprised of content that highlights major breakthroughs, discoveries, and authoritative research results as they pertain to all aspects of organizational growth and development. The chapter focuses on the new generation of Business Intelligence systems, i.e. self-service analytics and data visualization systems – Data Discovery, where data is primarily used for the reporting purpose, answering the question “what happened”. An executive dashboard developed in Tableau served as an example of the possible employment of this type of software in resource management of a selected not-for-profit organization.

Future research studies into the problems covered in the chapter may deal with the implementation of the DD systems in other organizations of the third sector of the national economy, or move on to the next step of the analysis, which helps to discover “why did it happen?”. Other issues worth further investigation include mobile business analytics systems and the adaptation of cloud-based business analytics. Today, research on the deployment of such technologies in this group of organizations is severely hindered by a lack of technological competence necessary to carry out the adaptations and high implementation costs.

5. CONCLUSION

The observation of transformations taking place in the economy and the ability to spot real problems pose a huge challenge for not-for-profit organizations. They necessitate organizations improving their operational as well as strategic performance. A good example is already set by state and private organizations, which widely adopt modern analytics methods, controlling tools and IT solutions for management purposes. They have developed capacity to make decisions due to perceptive diagnosis of the existing situation and thorough analysis of high-quality data derived from within the organization and from its environment. Data Discovery Systems mirror modern approach to data analytics, improve management and thus increase the benefits gained through better access to information and proactive response to the threats that organizations face in the daily performance of principal processes (incident handling) and in the management of other resources, indispensable for the implementation of these processes (human, financial and physical resources). Due to the ever-growing interest in civil society and the necessity for not-for-profit organizations to improve their operations so that they resemble commercial companies, an attempt was made to develop a managerial dashboard for these organizations. The dashboard, which was built in Tableau, a Data Discovery system, was designed for the Volunteer Fire Department. It focuses on the management of operational activities, human resources and finance. The dashboard had to be designed as the market does not offer any IT solutions that allow efficient management of this type of organizations. The dashboard validation proves that it facilitates access to the data the organization needs, information is generated in real time, and dashboard deployment does not require that the users be IT experts and the organization have complex IT infrastructure.

Obviously, the dashboard implementation falls at some hurdles. One of them is lack of awareness that data collection and data utilization are of vital importance in the management of this type of organizations, and that today no effective decisions can be made unless they are data-based. Another one is a low level of modern ICT usage in these organizations.

It was noticed that the dashboard can be expanded by adding analyses regarding e.g. the organization's fixed tangible assets. The improvements are planned to be made in the next stages of the research project.

The research methodology can be deployed in studies into other organizations of the third sector of the national economy in Poland, and their findings can be used to compare Polish organizations with their counterparts in other countries.

KEY TERMS AND DEFINITIONS

Asset: Something that has potential or actual value to an organization.

Business Intelligence System: A set of technologies, applications and practices related to the collection, integration, analysis, and presentation of business information to support business decision making processes.

Data Discovery (DD) System: A self-service Business Intelligence system.

Executive Dashboard: A computer interface that organizes and presents information for managers in a format that is easy to read and interpret; helps in effective management of an organization.

Information and Communication Technology (ICT): Information systems and technologies for the processing and communication of information.

Information System (IS): A computer program; enables and facilitates computer users to solve their problems.

Intangible Assets: Non-physical assets such as intellectual property.

Physical (Tangible) Assets: Within a business context, a physical asset might include a company's production equipment, its liquid funds, its product stock, and any property it owns.

Third Sector Organizations: Organizations established as a result of social initiative, motivated by a wish to serve people by satisfying their needs rather than a desire to make a profit.

ENDNOTE

¹ Efficiency refers to the relationship between the outcome, and the resources consumed and costs incurred to achieve it.

Agile Stage–Gate Hybrid Framework for New Product Development

3

Fotis C. Kitsios <https://orcid.org/0000-0001-7269-5567>*University of Macedonia, Greece***Maria Kamariotou** <https://orcid.org/0000-0002-7873-9265>*University of Macedonia, Greece*

INTRODUCTION

Since 1990, New Product Development (NPD) theory has considerably evolved distinct new practices, tools, techniques, and management frameworks (Cooper, 2019; Summers & Scherpereel, 2008). New products screening models have been developed such as a study that compared US and UK manufacturing firms and which depends on the type of product (old or new). This approach was used by Xin et al., (2008) so as to compare British and German machine tool manufacturers. This discriminating method was used in the field of NPD and especially in Phases I and II of Project SAPPHO and Project NewProd Phases I and II in order to compare new products in different industries. However, a complete 100% implementation of a product development process might be a misnomer as all processes are to be both flexible and situational so that they could match the dynamics of technologies, markets, and organizations (Biemans et al., 2015). Thus the search for appropriate NPD models or different approaches has become a new emerging topic both for scholars and practitioners resulting from the new disruptive innovation environment which has challenged NPD theory and practice in recent years (Cooper, 2017; Summers & Scherpereel, 2008).

As many companies have no formal NPD systems yet, ad hoc systems provide decision makers with too many discretion which leads to mistakes. So, some companies have opted for managing NPD within a formal system in an attempt to avoid those mistakes. Yet, a need to adapt Stage-Gate models is pointed out so that higher levels of flexibility and agility can be achieved (Conforto & Amaral, 2016; Ettlie & Elsenbach, 2007). The Stage-Gate model is the world's most widely benchmarked, referenced and implemented innovation management model which has been used by companies of all sizes and it has adopted in many industries. This model is used in order to help companies to develop and launch successful new products. Despite the positive effects that this model had in many companies, Stage-Gate has attracted a number of criticisms. It focuses on the financial perspective of NPD process, it is rigid and linear and it cannot handle innovative projects (Cooper, 2014).

One of the latest results of these researches on NPD management is agile NPD, which has recently, in the early 10's emerged in an attempt to manage the increasing complexity of the NPD process. The agile methods originate from the software development industry and are being increasingly adapted by research and development industrial companies, amongst others. Software development is almost infinitely divisible and consists of million lines of code that can be broken down into one hundred increments of approximately 10.000 lines, each increment yielding a working product. It is more than obvious, that

DOI: 10.4018/978-1-7998-3473-1.ch041

physical product development is something much different. The development of a new machine for example, or a new food product, or a polymer cannot be incrementalized. In such a way, therefore the concept of short time-boxed sprints cannot be applied as well (Cooper, 2014).

Recent academic findings show that agile methods are applied within the context of existing Stage-Gate NPD models. Also, what is indicated by the findings is that NPD performance is significantly improved after the implementation though rather than replacing the existing NPD standards, the agile framework is just emerged into them (Sommer et al., 2014). But studies regarding the transformation of the product development process and the integration of agile systems in the NPD process are limited. To this view, the main research questions are: Can agile be integrated with a traditional Stage-Gate model? And can the resulting hybrid model also be used for the development of physical products? (Cooper, 2017; 2016; Cooper & Sommer, 2016).

Thus, the purpose of this chapter is to provide a systematic approach regarding the implementation of the Stage-Gate model and agile software in NPD process. Authors derived recommendations for practitioners who want to study Stage-Gate and agile methods in NPD and a research agenda for academics that highlights the need for further research in this area. In addition, the resulting systematic overview is useful as a reference work for researchers in the field of NPD and helps them identify both related work and new research opportunities in this field.

The reminder of the chapter has been structured as follows: The next section describes the theoretical background regarding Stage-Gate and agile manufacturing. Then, solutions and recommendations for practitioners are discussed in next sections. Finally, conclusion and suggestions for future research conclude the chapter.

BACKGROUND

Stage-Gate Models

The NPD process is usually described as a complex set of activities taken up with a view to reduce the uncertainty regarding market needs and product process technological choices (Biazzo, 2009; Van Oorschot et al., 2010). Specific challenges that industry usually faces can be the dynamic volatile and unpredictable nature of demand, short life cycles of products, high levels of product variety and frequent product range changes and complex extended global supply chains requiring quick responsiveness to trends. Another not only significant but also gradually challenge for the industry is cost of excessive and underperforming innovation, though, that does not enhance performance and hence is superfluous rather than functional. This can be caused either by excessive NPD that dilutes overall profit margins or by design and development costs that exceed the product margin. A large number of low volume product can also be a factor since this can significantly damage relationships with vendors (Baker & Bourne, 2014; Ettlie & Elsenbach, 2007; Gunasekaran, 1999; Kettunen, 2009; Leite & Braz, 2016; Sommer et al., 2015).

Strategically, what provides real competitive advantages for a firm drew new products well attuned to the voice of the customer, with perceived technical superiority and developed within budget while launched ahead of the competition. If managers want to increase the success rate of their new product efforts, they have to master techniques for planning, development, evaluation and control of necessary competencies throughout the NPD process, literally speaking from the generation of the new idea to launch of the product at the marketplace (Fredberg & Piller, 2011; Tzokas et al., 2004). Implementing formal processes in NPD improves teamwork communication. It also has a positive impact on new

product success rate, on its better launch and earlier detection of failures as it improves time efficiency that is shorter elapsed time to launch (Cooper, 2008).

In actual fact the element of risk of high failure rate is embedded in NPD process, so it has been acknowledged by managers that effective product evaluation is a critical factor in successful new product programs. A method of managing the risks of new products is to introduce the evaluation gate that takes place between each development stage. Using the evaluation criteria within the gate managers can assess performance from corresponding development stage in order to determine the go/no-go decision and boost the accuracy of the project (Boly et al., 2015; Chao et al., 2014; de Brentani, 2001; Onarheim & Christensen, 2012; Schultz et al., 2013; Tzokas et al., 2004; Van Oorschot et al., 2010; Wang & Lee, 2011; Wang et al., 2012).

In this view, a Stage-Gate NPD process need to find the balance between innovation and control in order to grow profits and avoid underperforming NPD striking the correct balance is crucial to drive portfolio productivity as well as to improve the financial returns on investments made to build the portfolio (Baker & Bourne, 2014). A great deal for firms that currently develop new products using the Stage-Gate or any other similar process is to improve and control NPD (Sethi et al., 2012). The Stage-Gate model is the world's most widely benchmarked, referenced and implemented innovation management model which has been used by companies of all sizes and it has adopted in many industries. This model is used in order to help companies to develop and launch successful new products. It was designed including stages and gates that provide a holistic view of the idea to launch process that allow rapid, profitable and successful NPD (Stage-Gate International, 2019). Figure 1 presents the Stage-Gate model.

Figure 1. Stage-Gate Model

Each stage includes unique activities that can be implemented cross-functionally and iteratively in order to measure the business impact through the product design activities. Seasonal strategy planning, concept development, product specification development, physical prototype development, final range review and launch at the market are the typical key stages in product development. What is dictated by a systems approach is that there must be input and output as well as feedback and feedforward loops at each stage of the process (Bendoly & Chao, 2015; Baker & Bourne, 2014; Cooper, 2008; 2006; de Brentani, 2001; Karlstrom & Runeson, 2006; Sethi et al., 2012; Wang & Lee, 2011; Wang et al., 2012). Strategic goals, quality/value, people, process, customer and revenues/costs are included in the dimensions of metrics in gates. Only if the evaluation is completed and meet the criteria a project pass into the next stage. The process is controlled by many gates that include quality control checkpoints in order to assess the production process (Wang & Lee, 2011; Wang et al., 2012).

A set of criteria are used in gates in order to evaluate the process. More specifically, in the idea of screening gate managers have to evaluate the technical feasibility and uniqueness of the product idea concerning the market potential and perceived customer acceptance. The aim of this gate is to select the “right” ideas for further exploration. In the concept-testing gate, the idea is assessed according to customer acceptance and technical feasibility to decide whether to proceed with a formal business analysis of the product concept or not. In this stage, managers aim to collect more information regarding the technical characteristics of the idea. Next, in the business analysis gate managers have to decide if the project is going to be continued or not, so they focus on criteria such as sales objectives, sales in units, margin, and profit objectives set by management. In the product testing gate, managers evaluate the developed product according to the quality, the performance of the new product and its technical feasibility. This stage is crucial because managers have spent a part of the initial budget and the available resources which will be reduced in the launch stage. So they have to think if they have to decide on continuing the project or not. In the test market gate, the prototype of the product is available to the potential customers who give feedback to managers according to the product. The most frequently used criteria are the performance of the product, its quality, the customer acceptance and satisfaction. In the launch gate, managers consider of customer satisfaction in the long term, so the criteria used are customer satisfaction, sales objectives and market profit (Carbonell-Foulquié et al., 2004; Tzokas et al., 2014; Wang & Lee, 2011).

The last decades, next-generation of Stage-Gate model was developed in order to fluid requirements and to provide the right level of control. The next-generation of Stage-Gate is adaptive and it aims to be more agile, vibrant, dynamic, flexible gating process that is leaner, faster, and more adaptive and risk-based. It includes spiral or iterative development in order to produce new products that are based on customers’ requirements. Furthermore, this system is more flexible because it adopts market needs. Managers try to identify the risk in the beginning of the process. The next-generation idea-to-launch system is also agile because it produces deliverables that can be demonstrated to stakeholders. Finally, this system is focused on accelerating the development process. Employees for different business functions of a company participate in order to increase the speed of product development. In this system the stages are replaced by the fuzzy front end approach (Cooper, 2017; 2014).

Agility Software Development and Principles

In an attempts to define Agile Manufacturing (AM) researchers could state that it is a production model aiming at responding to changes of the environment with a view to providing flexibility, speed, quality, service and efficiency via the combination of high tech; highly qualified human resources and organization (Eklund et al., 2014; Gunasekaran, 1999; Karlström & Runeson, 2006; Leite & Braz, 2016). Electronics and software have been introduced into many products for the last two decades. More often, these products are developed in large, sometimes very complex, industrial projects with a more or less, elaborated R&D process which is governed by a Stage-Gate model in order to arrive at the finished design of the product (Eklund et al., 2014). This philosophy have profoundly affected companies as it can be seen from many perspectives: the one on companies that follow AM and have highly customized products that configure to one another; the one on companies that form relationships with long term customers that contribute to the development of products, also on those that have multidisciplinary teams capable of simultaneously developing product and production design. Other companies appeal to scientific knowledge and take support from production technologies, those who have modular production equipment and flexible and reconfigurable processes, on those that present strategic partnerships and

focus on customer satisfaction and finally those that have the ability to obtain and share inter-company and information quickly (Leite & Braz, 2016).

AM could be described as an integrated business concept consisting not only of the actual business planning and control but also of areas as business interfaces, supply chains and workforce factors. New product design is one particular part of it (Kettunen, 2009).

Nevertheless, what companies must be able to achieve, is to compete in sustainable ways. So, bearing in mind the considerations mentioned in the previous section the concept of AM was conceived in the early 90's so that it could address them. Many of the AM principles are of general purpose and technologically independent by nature. Software product development and software production both have certain unique properties and profound difference in comparison with typical manufacturing operations. But how exactly these two fields are related how much cross-domain know edge could be shared is not obvious to a great extent (Kettunen, 2009; Leite & Braz, 2016).

Agility is not unique when it comes to manufacturing. Neither is NPD nor software development. Many industries need more adaptive operative capabilities when they face unpredictable changes in product demands and customer needs. These adaptations are the key driver to flexible manufacturing systems. So, eventually the entire value network of the company, including the NPD function and the software development, can be viewed with respect to agility by following that line of strategic thinking (Kettunen, 2009). Software production has certain intrinsic characteristics traits when compared to manufacturing and NPD in general. Those are the potentially very fast (order of hours) development cycles (time of change), the fact that there are usually no physical rework constraints (cost of change) that radical redesigns are possible even at a late stage (magnitude of change). As a result, some of the limitations of traditional (hardware oriented) product development can fundamentally wait around, thus enabling a radical NPD process along with the accompanying management principles. This is where the current agile software development model basically stems from (Kettunen, 2009).

What determines the overall mode of operation of a manufacturing company is its strategy. This strategy should be shaped according to the competitive environment drivers by an intelligent agile manufacturer. Then, the strategic mode of operation could be set along with the dimension of "change proficiency" and "speed to customers" (Kettunen, 2009; Leite & Braz, 2016). Seeing agility from the company's wide strategic point of view is the key to truly mastering it both in manufacturing and NPD software development. The net-effect of the whole value chain is the flexibility (agility) of the company product creation and manufacturing. The overall company strategy consists of a hierarchy of sub strategies which are the function one. It is the function strategy that determines how the manufacturing part operates. In the same way there should be a function that defines how the software product development operates, bearing in mind through that it is important to understand the nature of that software development (Schuh et al., 2018).

A company's strategy based on added value so as to satisfy the customer with highly customized products of high quality is linked with the principles of AM. These principles require flexible processes, speed of response from suppliers, reduced life cycle of processes, business corporation within the supply chain, use of high tech and highly qualified human resources. So, briefly, the company with the most favorable condition for the application of AM is the one that differentiates the product offering in contrast with the competition. Such a company operating under the AM is one with a competitive strategy based on differentiation, which can be achieved by product development teams. It is their work which will be the key to the success of this strategy (Chuang et al., 2014; Leite & Braz, 2016).

FOCUS OF THE ARTICLE

Agile Manufacturing and Stage Gate Integration

The importance of adapting and combining AM practices with more traditional NPD processes (e.g. Stage-Gate) so as to improve flexibility and response to changes in uncertain and dynamic project management has been shown by recent studies. By eliminating activities that add no value to the product development and by using a minimal set of rules, agile methods can be focused on flexibility. These methods are based on a series of iterative development cycles, promoting self-management and self-discipline attitudes, so as to help the team to be readily responsive to changes. Different approaches, such as iterative development, should be considered by managers so that they could deal with different types of projects. It can be seen from this perspective that the combination of AM and Stage-Gate approaches could be explored as alternatives when dealing with the challenges of managing product development projects in highly dynamic business environments (Ciric et al., 2018; Conforto & Amaral, 2016).

NPD for manufacturers cannot be sufficiently supported only by agile. This is may a great deal of manufacturers of products from food to machinery are becoming more and more interested in hybrid development processes that combine agile with Stage-Gate, even IT development is not involved. Some of the early adopters of this method have already found out that the benefits of adopting such a hybrid approach are significant. This approach contributes to flexibility in product development, to high level of differentiation, to high customization levels in some product lines and to the involvement of different teams depending on project (Cooper, 2017; 2016; Cooper & Sommer, 2016).

The idea-to-launch process is broken into a series of five or six discrete stages by the Stage-Gate. These stages begin with the “idea generation” and more to “product launch” and beyond. Stage-Gate model is cross-functional and it involves people from marketing, sales and operations as well as the technical personnel but when the fact that each stage is a gate where decisions to invest or Go/Kill are made by analyzing whether managers are doing the right, proceeds then such a model is seen as being to linear, too rigid and too planned. For all these reasons is concerned to be unsuitable to deal with today’s fast-paced and, more often than not, quickly changing worlds (Cooper, 2016). So questions such as how reductions in particular stage times impact value or whether time reduction efforts should focus on particular stages in the process have to be answered (Bendoly & Chao, 2015). Early commitments to large features, long schedules, long feedback loops and the replanning, which are inherent to traditional product development processes, create inefficiencies and slow the development cycles. Agile methods offers both greater efficiency and focus, and Stage-Gate provides with a means of coordinating with other development teams and with a communication with functions such as marketing and senior management

Table 1. Comparison between Stage Gate and Agile method

	Stage-Gate	Agile
Type	Macroplanning	Microplanning, project management
Scope	Idea to launch	Development and testing, can be expanded to pre-development
Organization	Cross-functional team (R&D, marketing, sales, operations)	Technical team (software developers, engineers)
Decision model	Investment model—go/kill decisions involve a senior governance group	Tactical model—decisions about actions for next sprint made largely by self-managed team

are of great importance (Cooper, 2016). In Table 1 a comparison between Stage-Gate and agile method is presented (Cooper, 2017; 2016; Cooper & Sommer, 2016; Prebble et al., 2008).

The Hybrid Model

Models combining the two processes have already been presented by researchers. These models are framework comprising the Stage-Gate model and five dimensions. These dimensions are: (1) phase and project deliverable model (PPDM); (2) project planning and controlling white board (PPCW); (3) weekly activity planning white board (WAPW); (4) project management software (PMS); and (5) simplified performance indicator system (SPIS). With intent to satisfy the requirements of each phase-review milestone (or phase gate) of the product development process, each project phase can have as many iterations as necessary.

The levels of this hybrid model are three. The first one is the Stage-Gate model, represented by for the entire project by the PPDM, its phases, milestones, and macro-deliverables related to the product and technology development phases. The second level refers to the iterative development, also called “sprints” in the Scrum agile method in which the deliverables from the product back login are break down (by the team) into smaller ones, or into tasks and also the order of development is both prioritized and defined during the iterative planning meeting (or sprint planning). There are time-boxed iterations, usually of a 15-day length, during which these tasks are performed. The general set of deliverables and tasks to be performed in each phase are represented by the PPCW which is a physical visual board that evolves during the project life cycle. PPCW could be compared with the product back log described in the Scrum Agile method. As for the third level, this is performed either on a weekly or on daily basis and it bears similarities to the iteration plan or the sprint back log. It is called WAPW and deals with the assignment and performance of daily or weekly tasks. All these three levels provide with information that can be registered in the PMS.

As soon as a new project has begun, the iteration cycles guided by the PPDM (Stage 1) starts by defining the main phases as well as the project deliverables. This is an important element as it aims at guiding the team into the main phases of the product development process. This is why all the main deliverables and documents that are considered as key outputs as for the product and the project that is executed are included in the PPDM. Needless to say that the previously mentioned elements have to be specifically related to the type of project and the particular industry sector.

After the definition of the PPDM and once the team has acquired a broader view of the macro-deliverables in terms of the project, the iterations are collaboratively defined by both the project manager and the team members. At this stage the iteration length, is defined. This length usually is a period of two weeks, that is to say 15 days but that is something basically dependent on the type of project so it can be different when necessary. According to this model the phase length that reflects the characteristics of the project type and of the industry sector is usually longer compared to the iteration length. The PMD is used in the IVPM2 so that project data and information regarding cost, schedule and progress can be documented and also registered, in order to help the team generate reports. These are useful for both the evaluation of the phase review meeting and the iteration performance.

After the PMS (Stage 3) is over, the deliverables must be broken down into activities and tasks that are to be executed during the iteration (sprint). They also have to be placed in the WAPW (Stage 4) so that the work that has to be performed on a weekly basis can be illustrated. During the fifth stage, the performance can be on a weekly or sometimes on a daily basis and this procedure is supported by rapid, focused team meeting which are called “stand-ups” or “daily Scrum”. In other words, what members

need to deliver and what the issues or challenges are, are regularly discussed by the team so that the project manager can proactively address these problems. So, at the next stage (Stage 6) with the help of the PMS the project manager is able to generate performance reports and provide the team with an overview of the project progress. Finally, based on this information, decisions considering the improvement of the process are made, both by the project team and the manager. They also discuss upcoming risks and obstacles in order to plan for the next iteration cycle (Stage 7) (Conforto & Amaral, 2016).

Cooper & Sommer (2016) conducted a case study in order to validate the Agile Stage-Gate model in LEGO. LEGO started an innovative new-product project, Story Starter which was an educational solution that aimed to create confident writers and readers in elementary schools. The product was digital so managers could not use the traditional Stage-Gate model and they need a hybrid development method. This method would increase customer interactions and improve project productivity. As the product was digital, the digital solutions group used agile methods for software development. The benefits were significant, so they decided to use these methods for the entire project. Managers decided to keep the strategic benefits of their Stage-Gate model, so they incorporate these systems. The team used sprints and scrums to develop the project. Sprint reviews were important in order to identify customers' requirements. The AM was incorporated into the project during the development phase and continued into the implementation phase in their Stage-Gate model. The team communication, the productivity were increased and problems were reduced.

What was found by the researchers though, was not only that integration did work, with both models having indeed been compatible but also that several major payoffs were yielded by this hybrid approach. The advantages of Stage-Gate and AM have been both well researched and documented. In this hybrid model customer feedback and unfinished product features are prioritized and drive the sprint circle. Sprint planning produces a realistic and achievable action plan for the sprint. Daily scrums ensure constant team communication as the team implements the planned tasks, and produces the next product increment. Finally, team empowerment is a side benefit of the daily scrums. Some challenges regarding the Agile Stage-Gate model is the poor of knowledge management across functions, resource allocation delays and the bureaucratic project documentation. Furthermore, the financial and business analysis should be done in the same way with the traditional Stage-Gate model and product requirements should be defined at the beginning of the process in order to reduce risks (Cooper, 2016; Cooper & Sommer, 2018; 2016; Sommer et al., 2015).

SOLUTIONS AND RECOMMENDATIONS

Although the benefits of the Agile-Stage-Gate hybrid development model are defined, hardware developers and manufacturers are not informed about the importance this new approach. What is required by this hybrid method is that the project team should early and cheaply develop a physical or visual project and quickly present it to the customers to get feedback. In contrast, the traditional Stage-Gate methods require that before development begins the problem should be both identified and defined by conducting investigators. So during these early stages, or "homework phases" the project team has to undertake all markets, technical and business assessments so as to be able to define the product and to justify the project financially, while in an agile or hybrid approach requirement do not have to be defined before development but they are gradually established being a part of the solution-finding process. An advantage of this method is that teams are forced to focus on large-finalised lists of requirements or features. Time-boxed sprints, and event time-boxed tasks within sprints, bring a sense of urgency to the development

project making project teams commit to certain deliverables at the beginning of each sprint and thus being under pressure to deliver them within the agreed timetable (Cooper, 2016).

The fact that agile method calls for daily meetings provide teams with powerful face-to-face communications which is far more efficient than what can be provided with written documents. Also fast and continuous feedback given by the customers in terms of a product features helps to the creation of a more efficient project and subsequently of a better product. The whole procedure leads to cross-functional and more effective teams that have good internal cooperation and communication- both elements frequently cited as the key not only to increased speed to market but also to higher success rates in NPD (Cooper, 2016).

FUTURE RESEARCH DIRECTIONS

Although it has arisen some case studies there is still a large gap in exploratory studies, it is essential that this gap should be bridged in order to better establish and develop the hybrid model. Future research is essential to be conducted so that starting points and practical examples of development and implementation of agile systems can be clearly stated in terms of the management of service oriented organisations (Mircea & Andreescu, 2010).

Researchers do not know for sure what the critical factors or characteristic of the team, the project environment and the organization that will favor the use of all practices, its tools and techniques are. It is highly likely that they may include team characteristics, people competencies, organizational culture, structure and available resources or probably technology uncertainty and market characteristics. For these potential factors additional investigation is strongly recommended. So, taking multiple cases into consideration what should be identified is firstly, the importance of these factors and secondly which of these might affect the adoption of hybrid frameworks under different organizational and project conditions (Conforto & Amaral, 2016).

As the importance of the service sector both in developed and developing economies has been on the increase, attention has focused on the problems of managing service organizations. At the same time, increasing customers expectations, competition and speed of technological development force service organisations to constantly look for new approaches to service design and to delivery. Opportunities to develop new, improved services are offered by new methods and technologies. This is why New Service Development (NSD) is regarded as an essential part of a procedure so as to profitability or viability of existing services via increased sales and cost reduction, to attract new customers and to create loyalty amongst existing ones (Raman et al., 2017; Smith et al., 2007).

However, there are many new services which fail to achieve their either financial or any other objectives resulting in customer dissatisfaction with potential long-term consequences. Research has shown that service organizations do not adopt formal process while the NSD process itself offers a considerable scope for organizational conflict, inefficiencies and poor decision making (Kitsios & Kamariotou, 2016a; b; Smith et al., 2007; Witell et al., 2014). Applying the Stage-Gate model in NSD an emphasis on the analysis of the products fit with organizational objectives and resources is provided. Also the emphasis of this model on decision points (gates) can be extremely helpful as without having appreciated the impact of design decisions the costs of progressing service design would be significant (Smith et al., 2007).

Not only NPD, but also servicing companies have to be re-organised if they wish to overcome the challenges of the 21st century. Nowadays the needs of customers are highly specific but at the same time are rapidly changing. Although they ask for high quality products that keep them not just fully

satisfied but also delighted they wish these products so be of a low cost. As long as a company wants to be competitive in the market so as to survive it should respond to these new, rapid, continuous but yet predictable changes. In this competitive environment a flexible, adaptive and responsive paradigm should be developed by future researchers who can combine agile software and the Stage-Gate model in order to evaluate its effectiveness in services. Case studies could be used to apply the hybrid model in different services (e.g. hospitality, financial, e-government) and provide recommendations to managers about the improvement of the NSD process (BüyüKözkan et al., 2004; Gunasekaran & Yusuf, 2002; Juhola et al., 2014).

CONCLUSION

The purpose of this chapter was to provide a systematic approach regarding the implementation of the Stage-Gate model and agile software in NPD process. Authors derived recommendations for practitioners who want to study Stage-Gate and agile methods in NPD and a research agenda for academics that highlights the need for further research in this area. In addition, the resulting systematic overview is useful as a reference work for researchers in the field of NPD and helps them identify both related work and new research opportunities in this field.

In general, independencies bring the software product development closer to the AM. In addition, many of the product design principles in AM (e.g. modularity, customization) can be directly applied to the software production. On top of that, enterprise level concepts such as collaboration, core competence management and workforce factors are basically technological independent (Kettunen, 2009). Although it has arisen some case studies there is still a large gap in exploratory studies, it is essential that this gap should be bridged in order to better establish and develop this philosophy. A lack of exploratory scientific research leads to conflicting and even contradictory perspectives of several authors (Conforto & Amaral, 2016; Leite & Braz, 2016).

Despite the great differences between structured and flexible approaches and the fact that literature concerning NPD framework is evolving, yet studies are limited when it comes to understanding the benefits and the limitations that derive from the combination of different practices through approaches that meet current state of technology and product development in today's changing and competitive business environments. So, allegedly there is a lack of empirical studies that could show whether the combination of Stage-Gate and AM can contribute to agility and consequently to better project and product development or not (Conforto & Amaral, 2016). One example that illustrates that is that researchers do not know for sure what the critical factors or characteristic of the team, the project environment and the organization that will favor the use of all practices, its tools and techniques are. It is highly likely that they may include team characteristics, people competencies, organizational culture, structure and available resources or probably technology uncertainty and market characteristics.

KEY TERMS AND DEFINITIONS

Agile Manufacturing: An organization which has developed tools, processes, and skills to develop products that meet customer needs and quickly respond market changes.

Agile Software Development: An approach which is used by organizations that combine requirements and solutions of software development to develop products enabling cross-functional teams and customers or end users.

New Product development (NPD): A holistic process which includes the stages of launching a new product to the market.

Software Design: A specification of a software artifact is developed in order to achieve specific objectives, intended to accomplish goals, using a set of primary components and subject to restrictions.

Software Development: A planned and structured process of designing, programming, writing, and testing the source code in order to create and support applications, frameworks, or other software components.

Software Development Process: The division of a software development project into distinct phases in order to meliorate project management, product development and product design.

Software Prototyping: The development of prototypes of software applications (e.g., incomplete versions of a software program which has not been developed yet).

INTRODUCTION

There is a generalised consensus on the notable role that information systems and technologies (IS/IT) play in organisational performance (Mithas and Rust, 2016; Chen et al., 2014; Sabherwal & Jeyaraj, 2015; Wamba et al., 2017). The literature has traditionally associated the impact of IS/IT with technical and operational factors related to cost reduction and improved efficiency and productivity (e.g. Markus et al., 2000; Gattiker and Goodhue, 2005; Kale et al., 2010; Rouhani and Mehri, 2018). Recently, however, its impact seems to have been demonstrated in other management factors, such as those related to the satisfaction and motivation of human resources, their communication and internal coordination, their performance in decision making and in improving quality and services to clients (Shang and Seddon, 2000; Al-Mashari et al., 2003; Kale et al., 2010; Rouhani and Mehri, 2018) as well as strategic factors, linked to internationalisation (Morikawa, 2004), management of cooperation agreements (Sarker et al., 2012), organisational learning (Shang and Seddon, 2000) and innovation (Simao and Franco, 2018; Singaraju et al., 2016).

IS/IT support has thus led to the development and implementation of new organisational and inter-organisational business models (Loebbecke and Picot, 2015), which favour the creation of virtual clusters (Hernández and Peiró, 2013), improve the supply chain (Vendrell-Herrero et al., 2017), and even enable more sustainable strategies linked to the circular economy (Jabbour et al., 2017).

This evidence has been widely explored and recognised by both business practice and academia (Chen et al., 2014); as a result, the literature on information systems has acquired considerable relevance in the field of business administration due to its major role in the strategic process (Whittington, 2014). A growing number of journals now specialise in information systems and have a major impact in the field of management knowledge; some examples are MIS Quarterly, Journal of Information Technology, Journal of Strategic Information Systems, Information & Management, Information & Management, Journal of Management Information Systems, and Information Systems Research.

In order to observe the impact of information systems research on the scientific community, we carried out a bibliometric study based on an analysis of the concurrences (Lou and Qiu, 2014) of the key words used in publications on the subject. This type of quantitative analysis can reveal the structure that supports a certain topic in a discipline and its evolution, as well as the most relevant related concepts.

DOI: 10.4018/978-1-7998-3473-1.ch042

Figure 1. Network of key concepts with the greatest concurrence linked to information systems (period 2016-2019)

Our search strategy in the Scopus database was to first select all articles in the business, management and accounting category for the period 2016-2019 (up to 6 February 2019) whose keywords include information systems. This search yielded an input of 1,778 scientific articles. We then analysed these articles using the VOSviewer program to identify the most frequent keywords, which are highlighted in the figure and tables below.

Specifically, Figure 1 displays the nets, while Figure 2 displays the densities of the nets. Both figures were created by taking the 7737 keywords (introduced by the authors), filtered to obtaining a minimum of eight occurrences; this process resulted in 42 keywords related to the information systems in the articles of the area of business, management and accounting.

Based on this information, the next step in this bibliometric study is to conduct a cluster analysis of these 41 concepts (Wang et al., 2006). Specifically, the program displays six clear groups of theoretical analysis, as shown in Tables 1-6. In what follows, these six clusters are described together with their main focuses of analysis and publications in the literature.

Figure 2. Density of concepts linked to information systems

BACKGROUND

The first cluster obtained, labelled **Data Analytics**, includes a series of tools and methods that allow the capture and, above all, the strategic processing and exploitation of data to support decision making (Shollo and Galliers, 2016). These tools provide valuable support to improve the exploitation of environmental opportunities and face threats.

This cluster brings together the literature on *big data*, *business intelligence*, *cloud computing*, *data mining* and *the Internet of Things*, which also includes specific applications for *accounting information systems* and *healthcare*.

In fact, according to authors such as Trieu (2017) many of the above terms – business intelligence (BI), business analytics, big data and data mining are used indistinctly in the literature. Gartner (2013) defines BI as a set of applications, tools, infrastructure and practices that allow the access and analysis of information to optimise performance and decision making. In other words, BI transforms information into knowledge for strategic decision making.

This cluster also integrates one of the most relevant concepts in the literature, after information systems, namely big data, which provides the necessary data structure and methodologies for strategic analysis (Kowalczyk and Buxmann, 2014).

Big data is closely interrelated with the analytical components of business intelligence (Chen et al., 2012), considered one of the most influential technologies in organisations for its decisive role in strategic management (Horkoff et al., 2014), in its dynamic capacities (Wamba et al., 2017) and adaptation to the market (Enrevelles et al., 2016).

According to authors such as Chen et al. (2012), data analysis systems have evolved in different stages, from techniques such as accounting information systems, increasingly oriented towards the incorporation of both economic and social and environmental objectives (Schaltegger and Burritt, 2017; Dillard et al., 2016), to data mining for statistical analysis (e.g. classifying data, clustering them, analysing their associations, time series and other outliers) of large data aggregates, such as those derived from the most highly evolved systems, based on sensors and mobile applications; one example is the Internet of Things.

These authors highlight the widespread application of the advances in this type of computing to intelligent health and well-being, which demonstrates the importance of developments of information systems in the literature on health sciences, not only for the collection of data on patients, but for their analysis, research, diagnosis and treatment (Raghupathi, 2016; Wang, King and Byrd, 2018). These advances have an important impact for end customers and for public health policies.

Also linked to data analysis systems, cloud computing is conceived as a form of information technology outsourcing (Schneider and Sunyaev, 2016). It is a powerful technology that removes the need to maintain expensive computer hardware, dedicated space and software. This type of technology radically changes the way companies manage their IS components – applications, telecommunications, equipment and databases – in a customised environment with quality assurance (Wang et al., 2008). Such is the rise of these systems that a massive growth has been observed in the scale of data or big data generated through cloud computing (Abaker et al., 2015).

The systems evolving in the Internet of Things, together with other information technologies related to robotics, artificial intelligence, networking and knowledge management, such as blockchain, form the basis of this new Industry 4.0 paradigm. The main goals of Industry 4.0 are to achieve higher levels of operational efficiency and productivity, as well as greater automation and customisation of production (Li, 2017). Therefore, although the bibliometric analysis does not report the concept of Industry 4.0 as a key word in the business, management and accounting fields, it should be recognised as a relevant subject to include due to the disruptive effects it is having on supply chains, business models, and business processes (Shafiq et al., 2016).

The second cluster, labelled **Intra and Inter-organisational Electronic Interchanges**, covers the literature on *social networks*, *e-commerce*, *e-government* and *e-business*. Other concepts integrated in this group, which largely determine the success of electronic media in the management of intra- and inter-organisational relationships, are the degree of *adoption and acceptance of technologies*.

E-business is any exchange of goods, services or information between several companies (business-to-business), or relations between company and consumer (business-to-customer, intra-company such as business-to-employee), with the administration (business-to-administration) or between two consumers (consumer-to-consumer). The OECD Handbook (2005) defines the term e-business “as actions that significantly introduce different organisational structures, in order to implement advanced management techniques, or establish new or substantial changes in strategic direction”.

The growing development of the Internet has favoured the diffusion of social networks as a means of collaboration, creation and sharing of knowledge, between organisations and individuals through web

and mobile applications. Specifically, the analysis of e-commerce through mobile devices has led to the incipient analysis of m-commerce (Shin et al., 2018). This impact is transferred to the organisational level in the creation of new processes and capacities, above all, linked to the management and satisfaction of consumer needs (Lee and Kim, 2017).

E-commerce has been highlighted as a key lever for the development and growth of small and medium-sized enterprises in both developed and developing countries (Kurnia et al., 2015).

A growing number of studies highlight the importance of social networks in improving the transfer and flow of knowledge among the employees of a company (Razmerita et al., 2016), and, therefore, the processes of knowledge management and organisational learning (Zhang et al., 2015).

According to Al-Hujran et al. (2015: 189) “Electronic government refers to the use of information and communication technology (ICT) tools and applications to enhance government transparency and accountability in public administration by improving public services delivery, access to information and services and public governance”.

The main objective of e-government is not to implement new IT systems to automate traditional public service processes, or to add a new online service delivery channels per se, but rather to improve transparency, accountability and public sector governance (Chatfield and Alanazi, 2015).

The adoption and acceptance of social networks and IT by users for both commercial and public service access purposes depends largely on their level of trust. Previous e-government research has therefore highlighted the importance of trust as a determinant of citizen adoption of these services (Al-Hujran et al., 2015; Venkatesh et al., 2016). Trust can be classified as trust in the entity providing the service, and trust in the technology through which the service is provided.

The influence of social networks has also spread to achievements in open innovation and co-creation (Singaraju et al., 2016) and creation of value for society, through actions of crowdfunding (Agrawal et al., 2015), which connects financing parties with the developers of a project, and crowdsourcing (Xu et al., 2016), which promote the development of technologies applied to the acquisition, integration and analysis of large data derived from different sources in urban spaces (e.g. sensors, vehicles, buildings and people) in order to protect people’s safety and prevent disasters.

Social networks have promoted consumer interaction and have driven the creation of rating forums, forcing companies to improve their practices and invest in innovation (Kim and Chen, 2015).

Finally, keywords such as case study and trust are also included in this group. Trust is again postulated as a key precedent for the success of both the organisation's use of technology (Söllner et al., 2016) and the social networks and e-commerce it establishes with end consumers and society in general. In this line, the marketing literature has extensively studied user confidence in electronic relations with companies, as well as user behaviour patterns in social networks (Chang, Yu, and Lu, 2015).

Dynamic Capabilities is the concept used to refer the third theoretical group covering the main constructs with the greatest concurrence in the literature, *information systems* and *information technology*, which denotes the centrality and impact of the topic, as well as the main constructs linked to the literature on dynamic capabilities such as *knowledge management*, *innovation* and *absorptive capacity*.

The literature on dynamic capabilities is grounded in the seminal works of Teece et al. (1997) and Eisenhardt and Martin (2000), and emphasises the processes and capacities of organisations to introduce new endowments of resources and capacities and/or to reconfigure and transform existing ones.

Knowledge management is now a very prolific line of research in information systems, encompassing both internal creation within the company and the acquisition of knowledge from sources external to it (Forés and Camisón, 2016). The use of IT/IS play an important role in the external creation and sharing of knowledge, facilitating the creation of the virtual communities necessary for open innovation (Cui et al., 2015).

Other processes covered by this knowledge management, in which IS/IT are necessary, refer to the sharing of knowledge within and outside the organisation (Loebbecke et al., 2016) and to the management and application of this knowledge for its subsequent exploitation to create value (Cegarra-Navarro et al., 2015), in terms of organisational (Simao and Franco, 2018) and technological innovation (Zhang et al., 2018; Subramaniam and Youndt, 2005). Specifically, the study by Parida et al. (2016) reveals that IT capabilities influence adaptive dynamic capabilities, networking and innovation.

Absorption capacity is defined by Cohen and Levinthal (1990) as the ability of the enterprise to value, assimilate and apply, for commercial purposes, knowledge from external sources. Zahra and George (2002) reconceptualised the construct significantly, defining it as the set of organisational routines and

Source: the authors, based on Scopus data

strategic processes by which companies acquire, assimilate, transform and exploit external knowledge with the intention of creating a dynamic capacity. Unlike Cohen and Levinthal (1990), who emphasise the phases of assimilation and exploitation of externally generated knowledge, Zahra and George (2002) focus on the study of the distribution and integration of internal knowledge, for which information systems are a key antecedent (Jansen et al., 2005; Camisón and Forés, 2010; De Mattos and Laurindo, 2017).

Specifically, studies such as those by Francalanci and Morabito (2008), Liu et al. (2013) and Zhang et al. (2018) highlight the important role of absorption capacities in the relationship between the company's information systems and technologies and its innovative performance.

However, the relationship between information systems and absorption capacity is reported to be recursive, and studies such as Trieu (2017) stress that absorption capacity contributes to success in adopting systems such as business intelligence, while Park et al. (2007) show that there is a direct and positive relationship between an individual's ability to assimilate new knowledge about ERP systems and his or her ability to apply it.

This cluster also includes the concept of *project management*, considered a specialised management technique to plan and control the development of projects related to knowledge management (Park and Lee, 2014; Brahami and Mata, 2018) and organisational innovation (Hornstein, 2015). This is an abundant line of research in the management literature, which explains its inclusion in this cluster of analysis.

The fourth cluster, labelled **Geographical Agglomerations, Sustainability and Tourism**, includes the powerful construct of *geographic information systems* (GIS), linked to *tourism* studies, and other concepts that emphasise the importance of networks between agents, especially *SMEs*, such as the *supply chain*, to obtain potential returns in terms of *performance* (economic or innovative) or *sustainability*, both of which are also integrated in this cluster of analysis.

A geographic information system (GIS) is a computer system for capturing, storing, consulting, analysing and displaying geospatial data. Geospatial data describes both the location and attributes of spatial features. This is an indispensable tool for today's tourism, due to its impact on resource planning and management, public health and agricultural management (Chang, 2017). This type of tool offers location services, maps and other geographic information.

This cluster also includes the growing analysis of the application of IS/IT to the design of intelligent city planning (smart cities) (Neirotti et al., 2014) linked to sustainability (Ahmad and Mehmood, 2015), as well as the provision of infrastructure and other resources to improve the attractiveness of a certain community or region (Jabbour et al., 2017), tourist destination (Wang et al., 2016), or even a developing country (Senyo et al., 2016).

The application of the most advanced IT/IS has also triggered debate on the digitisation of the supply chain (Vendrell-Herrero et al., 2017), and its institutionalisation through security protocols and standards

provided by blockchain technologies (Korpela et al., 2017). IT has also enabled the implementation of systems to manage relationships between the agents of this sustainable value chain, establishing more social and ecological practices in production processes, services and final products (Camargo et al., 2017; Srivastava, 2007). The study of sustainable supply chains has also had a considerable impact in the field of tourism (Xu and Gursoy, 2015) due to the growing concern of consumers, communities and governments for the development of sustainable business practices.

IT is therefore acknowledged as an important tool for pursuing sustainability, increasing the company's knowledge of its impacts both at the supply chain level (Gold and Schleper, 2017; Formentini et al., 2016; Ivanov et al., 2018) and territorial agglomerations linked to the circular economy (Jabbour et al., 2017), and at the corporate level, analysing their impact on the adoption of more sustainable business models (Majid, 2018; Rauter et al., 2017). In this line, Camargo et al. (2017) highlights the information capacities derived from an information system, in terms of improved communication and knowledge transfer between and through functions, which enables effective compliance with environmental requirements.

Sustainability represents a fundamental paradigm capable of addressing economic, social and environmental issues under the same construct (WCED, 1987). The first notions of this concept emerged in the 1960s (Clark et al., 2004) when the sustainability of current prosperity trends was questioned, given the increasing rate of exploitation of natural resources.

The fifth cluster, labelled under the main concept of **Enterprise Resource Planning** (ERP), integrates several generic notions, such as *decision making*, *information security* and *management information*. All of these concepts are linked to the adoption of ERP systems, which have been widely recognised and documented by both academics and professionals.

ERP is a program that integrates information from all departments and functions of the organisation, providing access to all employees who need information from anywhere in the company. The program consists of modules that collect information from each company function, which is then stored in a central database for subsequent access and processing by any person or function that requires it. The use of this program helps to prevent redundant and duplicated information, and enhances integration of the company's departments. It is not only about information itself; rather, it is about processes and information flow.

ERPs are made up of a series of core components that deal with the classic elements of most ERP systems, focused on internal operations such as accounting and finance, production and materials management, human resources or marketing and sales. ERPs can also include additional extensions (or extended ERP components) that meet the needs not covered by the main components and that focus mainly on external operations. These extensions include business intelligence, customer relationship management, supply chain management and e-business.

Decision Making	13
Information Security	13
ERP	12
Management Information	11

Source: the authors, based on Scopus data

On the basis of interdepartmental integration and cohesion, and with the main agents in the external environment, several studies point to the impact of ERPs on knowledge management (Acar et al., 2017; Migdadi & Abu Zaid, 2016). Security is another of the concepts integrated in this cluster, one of the critical factors in the success of its implementation and use (Gupta and Misra, 2016).

Data and information security are of paramount importance to the cloud user. Server message blocks (SMBs) that adopt cloud ERP services for their business needs are unaware of the ways in which a cloud provider stores the user's confidential information. According to Gupta and Misra (2016: 3) there are four problems in information security, namely data confidentiality, encryption, accountability and maintenance.

Finally, the sixth cluster, labelled **Quality**, groups all the literature on information systems and quality – such as *information quality*, *service quality* and *system quality* – and *user satisfaction*.

User satisfaction with the use of any IS or IT, either as an agent maintaining business relationships with a company through electronic means (e.g. Lin et al., 2016; Ghasemaghaei and Hassanein, 2015), or as a company employee (Laumer et al., 2017), is strongly determined by quality. Following authors such as Laumer et al. (2017) and DeLone and McLean (2003) this can be analysed through several prisms: a) the quality of the system, which comprises the desirable characteristics of the technology itself, such as ease of use, efficiency, navigation and reliability; b) the quality of the service, which represents the quality of support or assistance that users receive from the IS department and IT support staff; and c) the quality of the information, defined as the degree to which the information meets the user's expectations (in terms of accuracy, integrity, coherence, or relevance) and with the requirements of the particular activity in which the user is involved (Ghasemaghaei and Hassanein, 2015).

FUTURE RESEARCH DIRECTIONS

This co-occurrence analysis, based on hierarchical clustering and supplemented by two visualisation techniques, has yielded results that can be easily interpreted by practitioners and managers, showing

how the field of information systems is evolving in the management literature, and detecting new trends and relationships among key topics. We are hopeful that this study will provide valuable support for future work in this field.

Future studies could usefully explore the latest trends in the research on information technologies from other fields such as engineering, computer science, biology and even psychology to complete this bibliometric study.

CONCLUSION

The study aimed to provide and discuss the most outstanding trends and topics in recent years with implications for the short-term future linked to information systems in the field of management and business. The research developed a bibliometric analysis based on a literature review and co-occurrence analysis, considering articles published since 2016 in Scopus. Keyword co-occurrence can uncover the structure of science, its evolution and potential relevance to the discipline (Lou and Qiu, 2014). The keywords analysis yielded network and density graphs from which six theoretical clusters were observed and defined: 1) data analytics, 2) electronic intra and inter-organisational exchanges, 3) dynamic capabilities, 4) geographical agglomerations, sustainability and tourism, 5) ERP, and 6) quality.

KEY TERMS AND DEFINITIONS

Big Data: Refers to large data sets. The definition of the term may also include the specific tools for their processing and structured or unstructured analysis that facilitate business decision making by revealing new patterns, associations, and trends.

Blockchain: Is a system in which a record of different types of interactions (commercial or not) made in a chain and cryptographically signed are managed through a peer-to-peer network. It allows information to be transferred under highly secure standards, and with validation at each step.

Business Intelligence: Includes the tools, practices, and infrastructures necessary for the organisation, management and analysis of information, in a visual and customised way, to improve business decision making.

Cloud Computing: Is the practice of accessing and using remote servers hosted on the Internet to organise, manage, analyse, and deliver data. It removes the need to maintain expensive computing hardware, dedicated space, and software.

Data Mining: Is the technology that allows relationships and trends to be discovered through the analysis of amounts of data stored in databases.

Geographical Information System (GIS): Is an ensemble of hardware, software and geographic data that facilitates the capture, storage, analysis, and presentation of any type of information related to geography or spatial data.

Internet of Things: Comprises the array of all the devices and objects whose status can be queried or modified via the Internet, with or without the active participation of people. It therefore includes the Internet, cloud computing, mass data analysis and sensors, whose convergence will lead to automatic learning, remote control and optimisation of machines and autonomous systems.

Smart City: Is the designation given to a city that integrates procedures, actions and IT to enhance its sustainability in terms of providing better quality in its landscape, governance, urban services for citizens, environmental responsibility, education, etc., and reduces consumption and costs.

Organizations Operating in Real Time (Real-Time Enterprise) and the Role of IT as a Tool Supporting Their Management Systems

Jerzy Kisielnicki

Faculty of Management, University of Warsaw, Poland

Marek Michał Markowski

Faculty of Management, University of Warsaw, Poland

INTRODUCTION

An RTE is an enterprise processing information in real time – an organization focused on quick response to the needs of the market and client, fast decision making, transparency and immediate information sharing among internal groups (Borg 2011, Šibalija, 2018).

Competition within this time-frame has become crucial for many businesses and quick response is the key element of success in face of critical events minimizing costs and maintaining perfect quality of activities (Cundius & Alt, 2017). Specifically, there is the necessity to apply tools enabling access to critical information in proper time and place (Karnouskos & Colombo, 2011), which allows for quicker decision making (Olofson & Morris, 2013).

The functioning of RTE without support from IT technologies seems impossible. Yet, a number of organisational changes need to be conducted within the enterprise which will be ‘solidified’ by IT. The aim is, among others, to focus on the activities which produce a bigger value (Hongren et al., 2015) and allow for optimisation of business processes (based, among others, on Lean), defining goals and preparing analysis of the time courses (Kyte 2004; Brand, 2012), as well as modification of some specialists’ qualifications (Vasarhelyi, 2010).

On the basic level IT solutions for RTE should enable:

1. Monitoring of the enterprises and its surroundings in real time,
2. Access to information in real time,
3. Acceleration of business processes.

The main objective of this chapter is to shed some light in the determinants of IT systems for RTE. First, the basic RTE areas will be analyzed. Second, the IT requirements for these areas will be presented, including sets of proposed determinants. Finally, conclusions and future research will be proposed.

BACKGROUND

The constant changes in the market and the increase in competition make it necessary to dynamically adapt the way of running a business (Wirtz et al., 2007). Enterprises must develop business flexibility by adapting new business models (Sikri, 2015) and implementing effective innovations (Grauer et al., 2010; Zhou et al., 2018). Technological progress changes the way enterprises conduct business (Vasarhelyi & Alles, 2008), requiring the use of tools that provide access to critical information at the right time and the right place, supporting rapid decision-making (Azvine et al., 2005). The reduction of time delays becomes the goal and way to implement the real-time system (Kejariwal & Orsini, 2018).

Therefore, the competitive advantage of real time enterprises (RTE) results from responding faster than the others the changing business conditions and opportunities.

Real time economy already exists (Vasarhelyi, 2010) and regards numerous industries, from fashion (Luskham, 2011), through finance (Kekwaletswe & Lesole, 2016), to software production (Martínez-Fernández, 2018). Processing information in real time – i.e. RTE – is also the core of Smart Factory in the Industry 4.0 concept (Herrmann, 2018).

The aim of these activities is to identify new business possibilities, avoid failures and minimize delays of the main business processes (Polites, 2006), improve flexibility, speed and quality of decisions, client relationships, increase the return on investments, as well as to increase productivity of the staff at each level of the organization (Smith, 2009). For the functioning of RTE is related to the use of proper techniques of human resources management (Yuan, 2016).

Specifically, there is the necessity to apply tools enabling access to critical information in proper time and place (Karnouskos & Colombo, 2011), which allows for quicker decision making (Thorpe & Kerr, 2011).

RTE acts quickly due to the integration of internal and external data, information analysis and communication among business partners (Kuglin & Thielmann, 2005). This may be compared to a gigantic spreadsheet where new information is sent via computer systems used by the enterprise and its suppliers. (Ramaswamy, 2015). In the ideal RTE model (Snabe et al., 2009):

- information circulates within the enterprise and beyond, with no barriers;
- business processes are continuously being monitored and improved;
- gathered and processed information on business processes provides an incentive for quick response to changes in the enterprise and beyond;
- key business processes are flexibly automated, usually in compliance with in-built principles.

ORGANIZATIONS OPERATING IN REAL TIME AND EXPECTATIONS FOR IT

As already mentioned the functioning of RTE without support from IT technologies seems impossible. When considering the use of IT tools in the implementation of RTE, its basic areas should be analyzed: monitoring of the enterprises and its surroundings in real time, access to information in real time and acceleration of business processes.

Real Time Monitoring

Efficient management is only possible when we have information about the organization and its surroundings and the quality of the information is good (Albers, 2014).

Currently, many everyday business transactions are not being efficiently monitored and supervised (Yousef et al., 2018), although many values which used to be seen as static are now gaining increasing variability.

Monitoring of an organisation and its surroundings in real time regards, among others the organisation's ability for detection of critical events, reporting, making decisions and responding, as well as its perfect business insight (Cannata et al., 2009; Kyte, 2004, McNurlin et al. 2009).

Measurements of an organisation which may be conducted in real time and compared to target values allow to continuously measure the activities (Subramanya 2011, Tank, 2015) and secure immediate access to key business indicators (Kang et al., 2011).

It is expected that the real time information processing technology allows not only to continuously monitor almost each link in the supplies chain, from product design, through purchasing raw materials, production, transportation, storing, distribution and after-sale service (Atzori et al., 2010), but also to provide customers with real time remote monitoring of the services provision (Lai et al., 2018) or information about the condition of machines and equipment. (Nel & Jooste, 2018).

For example, manufacturing companies need to be informed in real time on orders status, location of transported products, etc.

Precise monitoring is related to generation of vast amounts of data (Song et al., 2017), which create the, so called, stream of events possible to be processed in real time (Zhang et al, 2018). So IT should detect situations vital or critical for a particular monitored area in real time, based on the, so called, events patterns (Garro et al., 2016; Macià et al. 2016).

Real-Time Access to Information

To make decisions, business users need quick and reliable information delivered in real time (Yuhanna, et al., 2006, Fong & Hang, 2011). The need to access data in real time regards numerous areas of business, such as customer service and sale (Anand, 2012), logistics (Yin & Khoo, 2007) or production (Chen and Tu, 2009).

The freshness of data in IT systems should only depend on business needs (Watson et al., 2006, Ioana, 2008, McKenna, 2011). Therefore, in case of an enterprise implementing RTE strategies information is delivered when it is needed, easily, in the proper graphic form and based on defined business rules (Rabin, 2003; Mathes, 2016).

Information may be sourced from IT systems of the enterprise, i.e. ERP, CRM, SCM, MES (Hwang at al. 2018) or various Business Intelligence solutions working in traditional ways and in real time. Especially real time analytics becomes more and more necessary (Andriole, 2012) when data should be analysed immediately when it gets to the organisation (Sandu, 2008), providing decision-makers with the most recent information on the operational and tactical levels (Tank, 2015), enabling immediate reaction (Davcheva & Benlian, 2018) or improved efficiency, being capable of servicing terabytes of data (Pareek, 2010), using effective visualization solution (Davcheva & Benlian, 2018).

For example, production companies must have real-time access to reports on their own and subcontractors production capabilities, stock status, planned orders, etc.

Acceleration of Business Processes

The enterprises implementing the RTE concept must be capable of conducting their business processes in real time (Ouarhim & Baïna, 2019), relying on the best information available from all sources and delivered immediately to the decision making spot (Olofson & Morris, 2013), in an automatic way comprising various systems, media and organization limits (Khosla & Pal, 2002).

The term “real-time process” is used when there is no or little delay between the process’s input and output (HBR-Report, 2014). On-line processes are discussed consisting in computerised and automatised workflows (Kaymaz, 2015).

Four basic types of delays in complex business processes implementation may be identified which may be serviced by applying IT technologies (Vasarhelyi et. al., 2010):

- Delays within processes – the time needed for execution of the process. They are minimized by automation of subsequent steps in the process,
- Delays between systems: the time of transferring data between processes,
- Delays in decision making: the time needed to make decisions,
- Delays in implementation of already made decisions.

It is often believed that effects of IT functioning are best visible on the level of business processes (Ray et al., 2005). IT should reduce the execution time of business processes and shorten the time of making decisions (Ward & Honggeng, 2006) and, properly implemented, it give a competitive advantage (Powell & Dent-Micallef 1997). Automation of business processes reduces delays in their performance because the human-executed processes take minutes or hours and their automation allows for reduction of the execution times to some fractions of a second (Chan et al. 2009, Teeter & Vasarhelyi, 2010).

For example, in the automotive industry, a customer who wants to buy a new car after its configuration can receive the exact date of pickup of the car within a dozen or so minutes. Such a fast speed of information delivery results from the integration of SCM, ERP, etc. systems of producers and their suppliers.

SOLUTIONS AND RECOMENDATIONS

IT in RTE Implementation

The RTE concept implementation may involve enterprises in various industries, even very narrow ones. Therefore, to meet the RTE objectives it is necessary implement and modernize integration of various information systems. The nit may be concluded that the IT system servicing RTE will be a system of systems (as mentioned in the literature, for example by Hofman & Bastiaansen, 2014).

An initial conclusion from the analysis of local and international companies is that in many industries there exist real-time or near-real-time business processes (Table 1). They are serviced by a number of IT systems integrated in various ways and the ERP was the most common system.

Business information may come from a variety of business IT systems, i.e. ERP, CRM, SCM, MES, SCADA, etc.). Real-time information may also be sourced from RFID tags and the IoT objects, which sometimes requires a very detailed definition of events.

Thanks to IT solutions acquisition of measurement-related data and its transformation into useful information becomes a simpler and more automated process. According to the recent trends, transac-

Table 1. Examples of real-time (or near-real-time) processes in various industries and IT solutions applied for their servicing, source: own research

No	Industry	Example of real-time or near-real-time business process RTE	Short description of procedures/ main process steps	Examples of applied IT systems
1	Finance	Credit card payment	Purchasing a product or service from an acceptant Authorisation Transaction provision Payment to acceptant	Card servicing systems, fraud detection, BI,...
2	Telecommunication	New client (technical servicing)	Selection of service, entering the agreement, SIM card activation, Propagation of card recognition	Call Center, CRM, Billing Systems, RMCA and rating, OSS (network layer), BI
3	Retail	Selling the product in the internet	Selection of product from the internet shop, choice of delivery and payment options, delivery	Internet Sales app, ERP, BI, logistics systems
4	Utilities, energy sector	Malfunctions reporting	Information about the network malfunction, reporting affected individuals, sending a repairs team	SCADA, call center, billing/ customer service system, Workforce Management Systems, ERP, BI
5	Manufacturing	Sale of a vehicle	Initial vehicle configuration, Final vehicle configuration, pricing, entering the agreement, date of receipt confirmation	CRM, sale support systems, ERP, SCM, BI.

tions processing and analysis in a real time enterprise (RTE) may be serviced by solutions relying on in-memory data bases.

As business processes support involving a number of functional areas of the enterprise require a big number of the organisation's IT systems the IT system integration enables coordination of activities in the scope of product design, supplies as well as supervision of production or dispatching activities.

Use of the quickly growing domain – Artificial Intelligence may be crucial for implementation of the RTE concept. On an advanced level the AI may be viewed in terms of support for the fulfilment of important business needs: business processes automation, obtaining an insight through data analysis, as well as actively involving the customers and employees, decision making support and monitoring, reporting, business analyses and R&D, forecasts.

Preparing an all-encompassing IT system for enterprise processing information in real time (a real-time enterprise) is a complicated matter. It may be concluded that to benefit from implementation of enterprise processing information in real time (RTE), i.e. primarily to secure monitoring of the enterprise and its surroundings, as well as real-time access to data and an acceleration of business processes, it is required from the information technology to:

1. Implementation of new or development of existing IT systems in the core areas of the business, i.e. finance, production, sale and distribution, and supplies.
2. Integration of the IT systems in the scope of business processes, information and human resources.
3. Secure IT tools for the change management and continues improvement of the enterprise's processes.

Based on the analysis of the literature on the subject for each of the fields listed above a set of determinants may be offered supporting creation of an IT system for RTE. The determinants are expectations/requirements towards IT.

Implementation of New or Development of Existing IT Systems in the Core Areas of the Business

To conduct business activities enterprises use a number of IT systems in particular areas, f.e. ERP for the main back office activities, CRM for managing customer relations, SCM for transportation, BI for reporting etc. From the point of view of RTE these systems:

- Support execution of the whole or a part of business processes
- Function as a source of data for other IT systems within the enterprise.

So it seems to be very important to analyse if the required for RTE functionalities may be fulfilled by existing enterprise systems, their integration or new IT systems implementation is needed. The proposed list of exemplary determinants for this field is as follow:

1. CRM systems: improving customer relations, better understanding of the customer behavior and needs, improving customer retention, obtaining guidelines regarding product development;
2. ERP systems: bookkeeping and managerial accounting, production management, materials management, sale management, maintenance and repairs management;
3. MES: production process management, status of production level activities, detailed operation schedule;
4. SCM: securing visibility and product movement tracing options, management of physical, logical and financial flows within and outside of enterprise, sharing information with business partners and customers.

Integration of IT Systems in the Scope of Business Processes, Information and People

Business processes usually flow through various IT applications and they often require human interaction and exchange of information. Combining them, therefore, necessarily involves integration of human resources and information. IT technologies make it possible to share information and combine resources beyond the limits of the enterprise. From the point of view of RTE, integration of IT systems is needed for the reduction of delays in execution of business processes, access of information and efficient human labour.

Striving at integration and control of the enterprise at the same time requires ordering of organizational procedures and embedding methods of their execution in the applied information system.

IT integration, therefore, regards seamless interlinking of people, processes and information which may cross organization limits despite the existence of numerous potentially heterogeneous platforms and protocols, as well as numerous access devices.

The proposed list of exemplary determinants for this field is presented below:

1. Multi-channel service: securing the customers access to services and products via numerous communication channels, combining communication channels in an enterprise with the view of providing proper employees with up-to-date and coherent information, using information coming from one channel to make better decisions in other channels;
2. Portal: collective single window access to data and information, integrated access to applications, portal based automated work and documents flow, using collective tools for obtaining, coding, publication, search and sharing knowledge;
3. Co-operation: options for parallel work of people in various locations and time zones, supporting information sharing and informal communication, providing information about the status of co-workers' activities and increasing awareness of their activities, support for various types of work, i.e. meetings, presentations, sharing information with communities, screens sharing, collective notion of work space;
4. Business Intelligence: integration of a multitude of data coming from various sources, data provision to the user in the form and time favored by him/her, tracing processes and applications statuses, monitoring of key process indicators (KPI), quick access to original data coming from various systems, enabling work with integrated data, use of Real Time Business Intelligence (RTBI) – reduction of the decision-making time, applying BI for analysis of weak signals of approaching change, predicting future events (Predictive Analytics), use of Data Stream Management Systems for efficient processing of continues, infinite, varying in time data flows, including data mining.
5. Knowledge Management: securing the organisation's ability to obtain, manage and provide customer, product or service information in real time with the aim of improving the customer's responsiveness and guaranteeing faster decision making based on reliable data, support for the organisation's continues learning process and application of knowledge at hand, reduction of delays and challenges related to the bottleneck effect in terms of new products development, support for knowledge-based business processes, cooperation with other organisations due to improved quality and easier sharing of knowledge, providing a single, integrated access point to all documents of the organization and its surroundings
6. Master Data Management: option for joint defining key data used in the enterprise IT systems, creating a standard model for the enterprise key information objects integration and management, securing high quality of data
7. Integration Brokering: option for data translation from one format to another, securing easy access of applications to data exchange mechanisms, remote function call, creation and combination of webservices, secure two-way data flow between various workflow systems, download of data from RFID, IoT, etc.
8. Business Process Management: options for modelling, configuration, execution, monitoring and adjustment/correction of business processes with IT applications, managing business processes exceeding the organization boundaries and beyond its applications, business events management (e.g. Complex Event Processing), performing analyses and studying relationships between numerous events and triggers, defining Key Process Indicators.

Securing IT Tools for Change Management and Continuous Improvements of the Enterprise Processes

Creating an IT environment implementing the RTE concept requires organizational change management and altering the existent IT solutions. This also involves subsequent changes – already within the functioning RTE.

Organisations are social systems. The way they tackle changes is crucial for the success and survival of the enterprise. Change is intermingled with risk and, therefore, needs to be efficiently managed.

Managing change may be defined as “a process of continuously reviewing the direction, structure and possibilities of the organization with the aim of catering to the continuously changing needs of internal and external customers” (Moran & Brightman, 2001). Efficient change in the organization involves such domains as: the employee, leadership, training and development, awards and recognition, culture, politics and IT systems.

From the IT perspective – in order to secure flexibility of business processes and quick response to the changing requirements it is essential to implement these changes to the current IT environment as quickly as possible. Changes, especially to big organizations involve substantive costs of maintenance, modernization and integration of IT systems.

In bigger organizations with a more complex IT architecture there is an absolute need for central management of the imposed changes – their planning and execution (e.g. relying on ITIL).

It is essential to guarantee interoperability of systems and safety resulting from proper execution of all changes. In the scope of each implemented IT projects there exists a change approval workflow regarding accountability of particular staff, documentation, division among developer, test and manufacturing jobs, authorizations, granting approval etc.

The proposed exemplary determinants for this field is presented below:

1. Ability for change management and business processes continues improvement: managing the processes of obtaining permits and documentation regarding changes in the organization, simple changes to business processes in IT, application of V-model linking tests to the prepared change documentation, optimal functioning of IT components, the need for possession, maintenance and securing proper quality of documentation of applied IT systems, securing ergonomics and comfort of work, proper users training, proper users attitude towards duties.

FUTURE RESEARCH DIRECTIONS

Preliminary research enterprises allowed to identify areas where real-time information processing is the most important. It is related to, among others with customer, law and technology requirements. Interesting cases were observed, among others in financial services, telecommunications, manufacturing and retail.

As part of the basic research, the proposed lists of determinants regarding IT support for RTE implementation are currently being checked among a specified group of enterprises.

For many companies, striving for RTE is not the main goal of the activity. It takes place on the occasion of the modernization of individual business areas based on IT and appropriate changes in the organization (change management and further improvement).

Also for each of the areas, the proposed lists of determinants can be extended and more detailed. This will allow for even more accurate understanding of the implementation of real-time processes in enterprises.

The proposed directions for further research should also include deepening research in the field of RTE implementation through the analysis of:

- a) new, currently developed functionalities of IT business systems;
- b) future development of information technology in the field of integration of business processes, people and information,
- c) detailed models for the provision of IT security and continuity, ability to manage change and continuous improvement.

The proposed set of determinants may be converted into the method of preparing the areas of the enterprise for real time information processing.

CONCLUSION

The ability to conduct real time operations is becoming more and more important in a number of industries. Therefore, the idea of RTE, an enterprise that processes data in real time, is becoming more and more important.

RTE requires, among others, monitoring of the enterprises and its surroundings in real time, access to information in real time and acceleration of business processes.

The basis for efficient work for each of these areas is IT. Therefore, it seems important to identify determinants for the IT environment that will ensure its proper preparation.

Identified determinants can be divided into three groups:

1. Implementation of new or development of existing IT systems in the core areas of the business,
2. Integration of the IT systems in the scope of business processes, information and human resources,
3. Secure IT tools for the change management and continues improvement

It results from the conducted research that the strongest impact of RTE supporting systems is observed in terms of immediate access of information, which translates into the ability for quicker decision making, as well as into a more dynamic conduct of business processes. The human and his or her competences emerge as the prime limits to the development. The specified earlier determinants may constitute the basis for analysis and creation of IT in Real Time Enterprise supporting its operations in competitive markets.

KEY TERMS AND DEFINITIONS

BI: Business Intelligence, IT system which use data to generate information and knowledge supporting the process of decision making.

CRM: Customer Relationship Management, IT system which manages customer relations, used at sale, marketing, customer service and contacts center.

Determinant: Factor that resolutely controls or affects what happens in a particular situation.
